# Preface

## 1 Preface and selection Guide

High performance memory devices form an integral part of the INMOS product range. The INMOS Memory Databook has been published to provide comprehensive information regarding the current range of INMOS memory devices.

The databook comprises a selection guide, INMOS overview and engineering data for the current range of commercial and military memory devices. Additional information is provided detailing military qualification, quality and reliability information and general information covering thermal performance, product numbering, packaging and ordering.

All INMOS military products are designed to satisfy the requirements of a military environment in terms of temperature and reliability under adverse conditions. The majority of the military versions of INMOS memory devices fully comply with MIL-STD-883C and the US Government Standard Military Drawing (SMD) Program.

In addition to memory devices, the INMOS product range also includes transputer products, digital signal processing devices and graphics devices. For further information concerning INMOS products, please contact your local INMOS sales outlet.

# INMOS

# **1 INMOS**

## **1.1 Introduction**

INMOS supplies high performance memory and microprocessor products to companies manufacturing systems in the United States, Europe, Japan and the Far East. The current INMOS product lines include very fast static random access memories (RAMs), microprocessors called transputers, colour graphics devices and digital signal processing devices.

The Company's fabrication facility is at Newport, South Wales with final test facilities located both at Newport and Colorado Springs, Colorado, USA. The corporate headquarters, product design team and worldwide sales and marketing management are all based at Bristol, UK.

## **1.2 Static RAMs**

INMOS designs and manufactures a broad range of fast static RAMs, ranging from 4K to 64K bits, in a number of configurations. Revenues from memory products in 1988/89 accounted for approximately one third of total revenues.

As microprocessors become faster, so the demand for fast memory products increases. Despite the semiconductor recession of 1985/86 the number of fast static RAMs shipped worldwide continued to grow throughout the period. The growth of the computer market, coupled with the increasing amount of memory in each computer, has led to the continued demand for static RAMs. From Dataquest's actual figures of \$330M in 1986 for the worldwide fast static RAM market ('fast' includes 70ns cycle time and above) it is anticipated that market growth will continue rising to \$839M by 1991.

## **1.3 Manufacturing**

All products are manufactured at the INMOS Newport, Duffryn facility which began operations in 1983. This is an 8000 square metre building with a 3000 square metre cleanroom operating to Class 10 environment in the work areas.

To produce high performance products, where each microchip may consist of up to 300,000 transistors, INMOS uses advanced manufacturing equipment. Wafer steppers, plasma etchers and ion implantors form the basis of fabrication.

## **1.4 Assembly**

Sub-contractors in Korea, Taiwan, Hong Kong and the UK are used to assemble devices.

## **1.5 Test**

The final testing of commercial products is carried out at the INMOS Newport, Coed Rhedyn facility. Military final testing takes place at Colorado Springs.

## **1.6 Quality and Reliability**

Stringent controls of quality and reliability provide the customer with early failure rates of less than 1000 ppm and long term reliability rates of better than 100 FITs (one FIT is one failure per 1000 million device hours). Requirements for military products are even more stringent.

## **1.7 Military**

Most INMOS static RAMs are available in military versions processed in full compliance with MIL-STD-883C. INMOS also supports the US Government Defense Electronics Supply Center (DESC) Standard Military Drawing (SMD) program and is an approved supplier of a range of the SMDs already established by DESC.

## **1.8 Future developments**

### **1.8.1 Research and Development**

INMOS has achieved technical success based on a position of leadership in products and process technology in conjunction with substantial research and development investment. R and D investment has averaged 18 percent of revenues since inception and it is anticipated that future investment levels will be maintained at this level.

### **1.8.2 Process developments**

One aspect of the work of the Technology Development Group at Newport is to scale the present technology to 1.0 micron for products to be manufactured in 1989/90. Additionally, work is in progress on the development of 0.8 micron CMOS technology.

A new process technology developed in Colorado Springs for an advanced range of 256K static RAMs and other products is currently being transferred to Newport. To achieve early expertise in this new process a new 64K static RAM, based on the new technology, is being brought into production.

## **1.9 Package developments**

Where surface mount technology is desirable, the range of fast 64K static RAM will also be introduced in SOJ packaging.

## CMOS

### High Performance 4K x 1 Static RAM

#### FEATURES

- INMOS' Very High Speed CMOS
- Advanced Process - 1.6 Micron Design Rules
- 4K x 1 Bit Organization
- 25, 35, and 45 nsec Access Times
- 25, 35, and 45 nsec Chip Enable Access Times
- Fully TTL Compatible
- Separate Data Input and Output
- Three-state Output
- 18 Pin, 300-mil DIP
- Single +5V  $\pm$  10% Operation
- Power Down Function

#### DESCRIPTION

The INMOS IMS1203 is a high performance 4Kx1 CMOS static RAM. The IMS1203 allows speed enhancements to existing 4Kx1 applications with the additional benefit of reduced power consumption.

The IMS1203 features fully static operation requiring no external clocks or timing strobes, and equal address access and cycle times. Additionally, the IMS1203 provides a Chip Enable (/E) function that can be used to place the device into a low-power standby mode.

The IMS1203M is a MIL-STD-883 version intended for military applications.

# IMS1203

## ABSOLUTE MAXIMUM RATINGS\*

Voltage on any pin relative to $V_{SS}$ . . . . .	-2.0 to 7.0V
Voltage on Q . . . . .	-1.0 to ( $V_{CC} + 0.5V$ )
Temperature Under Bias . . . . .	-55°C to 125°C
Storage Temperature . . . . .	-65°C to 150°C
Power Dissipation . . . . .	1W
DC Output Current . . . . .	25mA

(One Second Duration)

\*Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

## DC OPERATING CONDITIONS

SYMBOL	PARAMETER	MIN	TYP	MAX	UNITS	NOTES
$V_{CC}$	Supply Voltage	4.5	5.0	5.5	V	
$V_{SS}$	Supply Voltage	0	0	0	V	
$V_{IH}$	Input Logic "1" Voltage	2.0		$V_{CC} + 5$	V	All inputs
$V_{IL}$	Input Logic "0" Voltage	-1.0*		0.8	V	All inputs
$T_A$	Ambient Operating Temperature	0		70	°C	400 linear ft/min air flow

\*  $V_{IL}$  Min = -3.0V for pulse width <20ns, note b.

## DC ELECTRICAL CHARACTERISTICS (0°C ≤ $T_A$ ≤ 70°C) ( $V_{CC} = 5.0V \pm 10%$ )<sup>a</sup>

SYMBOL	PARAMETER	MIN	MAX	UNITS	NOTES
$I_{CC1}$	Average $V_{CC}$ Power Supply Current		80	mA	$t_{AVAV} = t_{AVAV}(\text{min})$
$I_{CC2}$	$V_{CC}$ Power Supply Current (Standby, Stable TTL Input Levels)		15	mA	$\bar{E} \geq V_{IH}$ All other inputs $V_{IN} \leq V_{IL}$ or $\geq V_{IH}$
$I_{CC3}$	$V_{CC}$ Power Supply Current (Standby, Stable CMOS Input Levels)		6	mA	$\bar{E} \geq (V_{CC} - 0.2V)$ All other inputs at $V_{IN} \leq 0.2V$ or $\geq (V_{CC} - 0.2V)$
$I_{CC4}$	$V_{CC}$ Power Supply Current (Standby, Cycling CMOS Input Levels)		13	mA	$\bar{E} \geq (V_{CC} - 0.2V)$ Inputs cycling at $V_{IN} \leq 0.2V$ or $\geq (V_{CC} - 0.2V)$
$I_{ILK}$	Input Leakage Current (Any Input)		±1	µA	$V_{CC} = \text{max}$ $V_{IN} = V_{SS}$ to $V_{CC}$
$I_{OLK}$	Off State Output Leakage Current		±5	µA	$V_{CC} = \text{max}$ $V_{IN} = V_{SS}$ to $V_{CC}$
$V_{OH}$	Output Logic "1" Voltage	2.4		V	$I_{OUT} = -4mA$
$V_{OL}$	Output Logic "0" Voltage		0.4	V	$I_{OUT} = 12mA$

Note a:  $I_{CC}$  is dependent on output loading and cycle rate. the specified values are obtained with the output unloaded.

## AC TEST CONDITIONS

Input Pulse Levels . . . . .	$V_{SS}$ to 3V
Input Rise and Fall Times . . . . .	5ns
Input and Output Timing Reference Levels . . . . .	1.5V
Output Load . . . . .	See Figure 1

## CAPACITANCE ( $T_A = 25^\circ\text{C}$ , $f = 1.0\text{ MHz}$ )<sup>b</sup>

SYMBOL	PARAMETER	MAX	UNITS	CONDITIONS
$C_{IN}$	Input Capacitance	4	pF	$\Delta V = 0$ to 3V
$C_{OUT}$	Output Capacitance	4	pF	$\Delta V = 0$ to 3V

Note b: This parameter is sampled and not 100% tested.

**RECOMMENDED AC OPERATING CONDITIONS** ( $0^{\circ}\text{C} \leq T_A \leq 70^{\circ}\text{C}$ ) ( $V_{CC} = 5.0\text{V} \pm 10\%$ )

**READ CYCLE<sup>g</sup>**

NO.	SYMBOL		PARAMETER	1203-25		1203-35		1203-45		UNITS	NOTES
	Standard	Alternate		MIN	MAX	MIN	MAX	MIN	MAX		
1	$t_{ELQV}$	$t_{ACS}$	Chip Enable Access Time		25		35		45	ns	
2	$t_{AVAV}$	$t_{RC}$	Read Cycle Time	25		35		45		ns	c
3	$t_{AVQV}$	$t_{AA}$	Address Access Time		25		35		45	ns	d
4	$t_{AXQX}$	$t_{OH}$	Output Hold After Address Change	3		3		3		ns	
5	$t_{ELOX}$	$t_{LZ}$	Chip Enable to Output Active	5		5		5		ns	j
6	$t_{EHQZ}$	$t_{HZ}$	Chip Disable to Output Inactive	0	20	0	30	0	30	ns	f, j
7	$t_{ELICCH}$	$t_{PU}$	Chip Enable to Power Up	0		0		0		ns	j
8	$t_{EHICCL}$	$t_{PD}$	Chip Enable to Power Down		20		20		20	ns	j
		$t_T$	Input Rise and Fall Times		50		50		50	ns	e, j

Note c: For READ CYCLE 1 & 2,  $\bar{W}$  is high for entire cycle.

Note d: Device is continuously selected;  $\bar{E}$  low.

Note e: Measured between  $V_{IL}$  max and  $V_{IH}$  min.

Note f: Measured  $\pm 200\text{mV}$  from steady state output voltage. Load capacitance is 5pF.

Note g:  $\bar{E}$  and  $\bar{W}$  must transition between  $V_{IH}$  to  $V_{IL}$  or  $V_{IL}$  to  $V_{IH}$  in a monotonic fashion.

Note j: Parameter guaranteed but not tested.

**READ CYCLE 1<sup>c, d</sup>**

**READ CYCLE 2<sup>c</sup>**

**DEVICE OPERATION**

The IMS1203 has two control inputs, Chip Enable ( $\bar{E}$ ) and Write Enable ( $\bar{W}$ ), twelve address inputs ( $A_0$ - $A_{11}$ ), a data in ( $D_{IN}$ ) and a data out ( $D_{OUT}$ ). The  $\bar{E}$  input controls device selection as well as active and standby modes. With  $\bar{E}$  low, the device is selected and the twelve address inputs are decoded to select one memory cell out of 4096. Read and Write operations on the memory cell are controlled by  $\bar{W}$  input. With  $\bar{E}$  high, the device is deselected, the output is disabled, and the power consumption is reduced to less than one-third of the active mode power with TTL levels and even lower with CMOS levels.

**READ CYCLE**

A read cycle is defined as  $\bar{W} \geq V_{IH}$  min with  $\bar{E} \leq V_{IL}$  max. Read access time is measured from either  $\bar{E}$  going low or from valid address.

The READ CYCLE 1 waveform shows a read access that is initiated by a change in the address inputs while  $\bar{E}$  is low. The output remains active throughout READ CYCLE 1 and is valid at the specified address access time. The address inputs may change at access time and as long as  $\bar{E}$  remains low, the cycle time is equal to the address access time.

# IMS1203

**RECOMMENDED AC OPERATING CONDITIONS** ( $0^{\circ}\text{C} \leq T_A \leq 70^{\circ}\text{C}$ ) ( $V_{CC} = 5.0\text{V} \pm 10\%$ )

## WRITE CYCLE 1: $\bar{W}$ CONTROLLED<sup>g, h</sup>

NO.	SYMBOL		PARAMETER	1203-25		1203-35		1203-45		UNITS	NOTES
	Standard	Alternate		MIN	MAX	MIN	MAX	MIN	MAX		
9	$t_{AVAV}$	$t_{WC}$	Write Cycle Time	25		35		45		ns	
10	$t_{WLWH}$	$t_{WP}$	Write Pulse Width	15		20		25		ns	
11	$t_{ELWH}$	$t_{CW}$	Chip Enable to End of Write	20		30		40		ns	
12	$t_{DVWH}$	$t_{DW}$	Data Set-up to End of Write	15		20		25		ns	
13	$t_{WHDX}$	$t_{DH}$	Data Hold After End of Write	0		0		0		ns	
14	$t_{AVWH}$	$t_{AW}$	Address Set-up to End of Write	20		30		40		ns	
15	$t_{AVWL}$	$t_{AS}$	Address Set-up to Beginning of Write	0		0		0		ns	
16	$t_{WHAX}$	$t_{WR}$	Address Hold After End of Write	0		0		0		ns	
17	$t_{WLQZ}$	$t_{WZ}$	Write Enable to Output Disable	0	15	0	20	0	20	ns	f, j
18	$t_{WHQX}$	$t_{OW}$	Output Active After End of Write	0		0		0		ns	i

Note f: Measured  $\pm 200\text{mV}$  from steady state output voltage. Load capacitance is  $5\text{pF}$ .

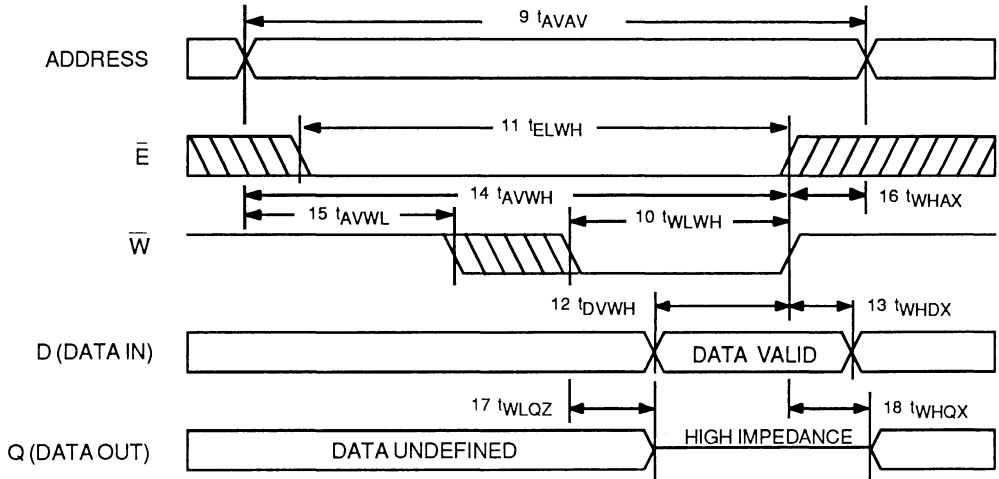

Note g:  $\bar{E}$  and  $\bar{W}$  must transition between  $V_{IH}$  to  $V_{IL}$  or  $V_{IL}$  to  $V_{IH}$  in a monotonic fashion.

Note h:  $\bar{E}$  or  $\bar{W}$  must be  $\geq V_{IH}$  during address transitions.

Note i: If  $\bar{W}$  is low when  $\bar{E}$  goes low, the output remains in the high impedance state.

Note j: Parameter guaranteed but not tested.

## WRITE CYCLE 1

The READ CYCLE 2 waveform shows a read access that is initiated by  $\bar{E}$  going low. As long as address is stable when  $\bar{E}$  goes low, valid data is at the output at the specified Chip Enable Access time. If address is not valid when  $\bar{E}$  goes low, the timing is as specified in READ CYCLE 1. Chip Enable access time is not affected by the duration of the deselect interval.

## WRITE CYCLE

The write cycle of the IMS1203 is initiated by the latter of  $\bar{E}$  or  $\bar{W}$  to fall. In the case of  $\bar{W}$  falling last, the output buffer will be turned on  $t_{ELQX}$  after the falling edge of

$\bar{E}$  (just as in a read cycle). The output buffer is then turned off within  $t_{WLQZ}$  of the falling edge of  $\bar{W}$ . During this interval, it is possible to have bus contention between devices with D and Q connected together in a common I/O configuration. Contention can be avoided in a carefully designed system. During a write cycle, data on the input is written into the selected cells and the output is floating.

WRITE CYCLE 1 waveform shows a write cycle terminated by  $\bar{W}$  going high. Data set-up and hold times are referenced to the rising edge of  $\bar{W}$ . When  $\bar{W}$  goes high at the end of the cycle with  $\bar{E}$  active, the output of

**RECOMMENDED AC OPERATING CONDITIONS** ( $0^{\circ}\text{C} \leq T_A \leq 70^{\circ}\text{C}$ ) ( $V_{CC} = 5.0\text{V} \pm 10\%$ )

**WRITE CYCLE 2:  $\bar{E}$  CONTROLLED<sup>g, h</sup>**

NO.	SYMBOL		PARAMETER	1203-25		1203-35		1203-45		UNITS	NOTES
	Standard	Alternate		MIN	MAX	MIN	MAX	MIN	MAX		
19	$t_{AVAV}$	$t_{WC}$	Write Cycle Time	25		35		45		ns	
20	$t_{WLEH}$	$t_{WP}$	Write Pulse Width	15		20		25		ns	
21	$t_{ELEH}$	$t_{CW}$	Chip Enable to End of Write	20		30		40		ns	
22	$t_{DVEH}$	$t_{DW}$	Data Set-up to End of Write	15		20		25		ns	
23	$t_{EHDX}$	$t_{DH}$	Data Hold After End of Write	0		0		0		ns	
24	$t_{AVEH}$	$t_{AW}$	Address Set-up to End of Write	20		30		40		ns	
25	$t_{EHAX}$	$t_{WR}$	Address Hold After End of Write	0		0		0		ns	
26	$t_{AVEL}$	$t_{AS}$	Address Set-up to Beginning of Write	0		0		0		ns	
27	$t_{WLOZ}$	$t_{WZ}$	Write Enable to Output Disable	0	15	0	20	0	20	ns	f, j

Note f: Measured  $\pm 200\text{mV}$  from steady state output voltage. Load capacitance is  $5\text{pF}$ .

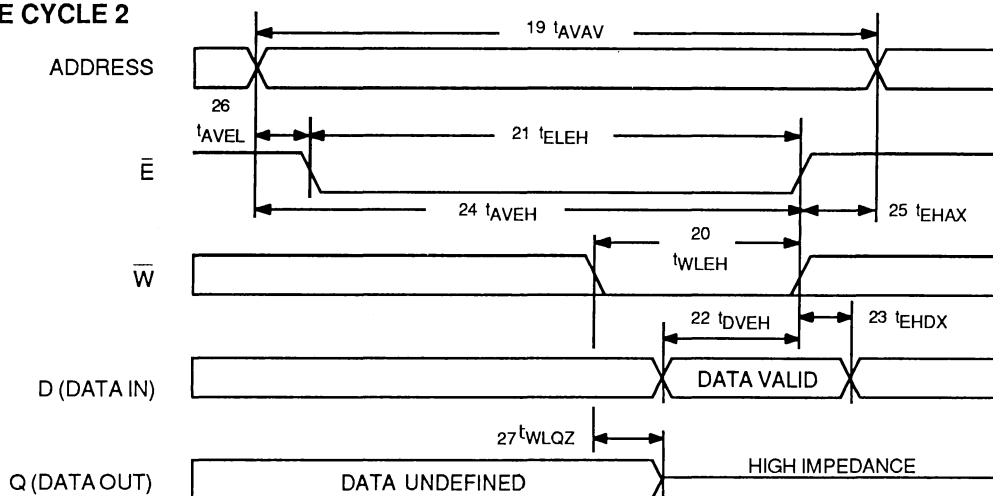

Note g:  $\bar{E}$  and  $\bar{W}$  must transition between  $V_{IH}$  to  $V_{IL}$  or  $V_{IL}$  to  $V_{IH}$  in a monotonic fashion.

Note h:  $\bar{E}$  or  $\bar{W}$  must be  $\geq V_{IH}$  during address transitions.

Note i: If  $\bar{W}$  is low when  $\bar{E}$  goes low, the output remains in the high impedance state.

Note j: Parameter guaranteed but not tested.

**WRITE CYCLE 2**

the memory becomes active. The data from the memory will be the same as the input data unless the input data or address changes.

WRITE CYCLE 2 waveform shows a write cycle terminated by  $\bar{E}$  going high. Data set-up and hold times are referenced to the rising edge of  $\bar{E}$ . With  $\bar{E}$  high, the outputs remain in the high impedance state.

**APPLICATION**

It is imperative when designing with any very high speed memory, such as the IMS1203, that the fundamental rules in regard to memory board layout be followed to ensure proper system operation.

**POWER DISTRIBUTION**

The recommended power distribution scheme combines proper power trace layout and placement of decoupling capacitors to maintain the operating margins of the IMS1203. The impedance in the decoupling path from the power pin (18) through the decoupling capacitor to the ground pin (9) should be kept to a minimum. The impedance of this path is determined by the series impedance of the power line inductance and the inductance and reactance of the decoupling capacitor.

Since the current transients associated with the operation of the high speed IMS1203 have very high frequency

## IMS1203

components, the line inductance is the dominating factor. To reduce the line inductance, the power trace and ground trace should be gridded or provided by separate power planes. The decoupling capacitor supplies energy for high frequency current transients and should be located as close to the devices with as short lead length as possible. The high frequency decoupling capacitor should have a value of 0.1 microfarad, and be placed between each row of devices in the array (see drawing). A larger tantalum capacitor, with a sufficient value to eliminate low frequency ripple, should be placed near the memory board edge connection where the power traces meet the backplane power distribution system. These larger capacitors provide bulk energy storage to prevent voltage drop due to the main supply being located off the memory board and at the end of a long inductive path.

The ground grid of the memory array should extend to the TTL driver periphery circuit. This will provide a solid ground reference for the TTL drivers and prevent loss of operating margin of the drivers due to differential ground noise.

### TERMINATION

Trace lines on a memory board in the array look to TTL driver signals like low impedance, unterminated transmission lines. In order to reduce or eliminate the reflections of the TTL signals propagating down the lines, especially low going TTL signals, line termination is recommended. The termination may be either series or parallel.

The recommended technique is to use series termination. The series termination technique has the advantage of drawing no DC current and using a minimum number of components. This is accomplished by placing a series resistor in the signal line at the output of the TTL driver to dampen the reflection on the line. The resistor should

be placed as close to the driver package as is practical. The line should be kept short by placing the driver-termination combination close to the memory array.

Some experimentation will have to be done to find the proper value to use for the series termination to minimize reflections, but generally a series resistor in the 10 to 33 ohm range will be required. Because each design will result in a different signal impedance, a resistor of predetermined value may not properly match the signal path impedance. The proper value of resistance should therefore be selected empirically.

# IMS1223 CMOS High Performance 1K x 4 Static RAM

## FEATURES

- INMOS' Very High Speed CMOS
- Advanced Process - 1.6 Micron Design Rules
- 1K x 4 Bit Organization
- 25, 35, and 45 nsec Access Times
- 25, 35, and 45nsec Chip Enable Access Times
- Fully TTL Compatible
- Common Data Input and Output
- Three-state Output
- 18 Pin, 300-mil DIP
- Single +5V  $\pm$  10% Operation
- Power Down Function

## DESCRIPTION

The INMOS IMS1223 is a high performance 1Kx4 CMOS static RAM. The IMS1223 allows speed enhancements to existing 1Kx4 applications with the additional benefit of reduced power consumption.

The IMS1223 features fully static operation requiring no external clocks or timing strobes, and equal address access and cycle times. Additionally, the IMS1223 provides a Chip Enable (/E) function that can be used to place the device into a low-power standby mode.

The IMS1223M is a MIL-STD-883 version intended for military applications.

Note f: Measured  $\pm 200\text{mV}$  from steady state output voltage. Load capacitance is 5pF.

Note g:  $\bar{E}$  and  $\bar{W}$  must transition between  $V_{\text{IH}}$  to  $V_{\text{IL}}$  or  $V_{\text{IL}}$  to  $V_{\text{IH}}$  in a monotonic fashion.

Note j: Parameter guaranteed but not tested.

**READ CYCLE 1<sup>c, d</sup>**

**READ CYCLE 2<sup>c</sup>**

**DEVICE OPERATION**

The IMS1223 has two control inputs: Chip Enable ( $\bar{E}$ ) and Write Enable ( $\bar{W}$ ), ten address inputs ( $A_0$ - $A_9$ ), and four data I/O lines. The  $\bar{E}$  input controls device selection as well as active and standby modes. With  $\bar{E}$  low, the device is selected and the ten address inputs are decoded to select one 4 bit word out of 1024. Read and Write operations on the memory cell are controlled by  $\bar{W}$  input. With  $\bar{E}$  high, the device is deselected, the outputs are disabled, and the power consumption is reduced to less than one-third of the active mode power with TTL levels and even lower with CMOS levels.

**READ CYCLE**

A read cycle is defined as  $\bar{W} \geq V_{\text{IH}}$  min with  $\bar{E} \leq V_{\text{IL}}$  max. Read access time is measured from either  $\bar{E}$  going low or from valid address.

The READ CYCLE 1 waveform shows a read access that is initiated by a change in the address inputs while  $\bar{E}$  is low. The output remains active throughout READ CYCLE 1 and is valid at the specified address access time. The address inputs may change at access time and as long as  $\bar{E}$  remains low, the cycle time is equal to the address access time.

18	$t_{WHQX}$	$t_{OW}$	Output Active After End of Write	5		5		5		ns	i

Note f: Measured  $\pm 200\text{mV}$  from steady state output voltage. Load capacitance is  $5\text{pF}$ .

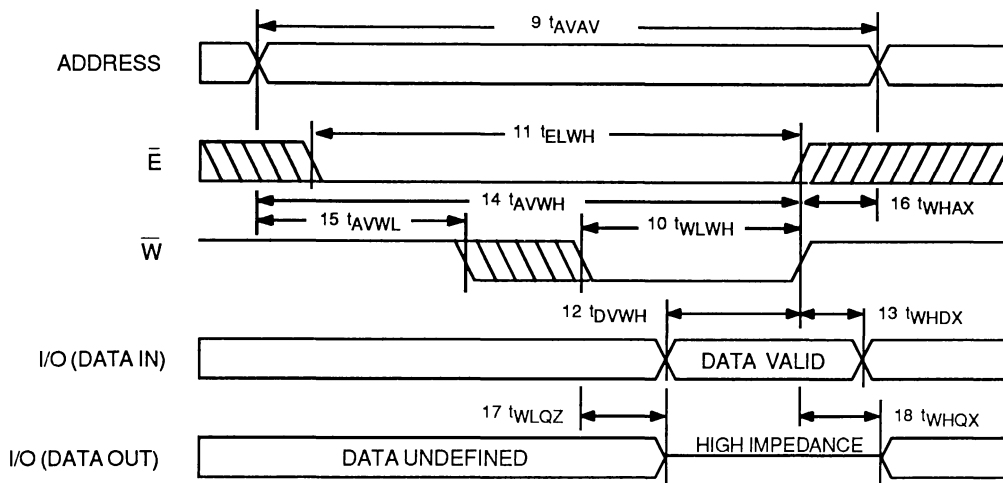

Note g:  $\bar{E}$  and  $\bar{W}$  must transition between  $V_{IH}$  to  $V_{IL}$  or  $V_{IL}$  to  $V_{IH}$  in a monotonic fashion.

Note h:  $\bar{E}$  or  $\bar{W}$  must be  $\geq V_{IH}$  during address transitions.

Note i: If  $\bar{W}$  is low when  $\bar{E}$  goes low, the outputs remain in the high impedance state.

Note j: Parameter guaranteed but not tested.

### WRITE CYCLE 1

The READ CYCLE 2 waveform shows a read access that is initiated by  $\bar{E}$  going low. As long as address is stable when  $\bar{E}$  goes low, valid data is at the output at the specified Chip Enable Access time. If address is not valid when  $\bar{E}$  goes low, the timing is as specified in READ CYCLE 1. Chip Enable access time is not affected by the duration of the deselect interval.

### WRITE CYCLE

The write cycle of the IMS1223 is initiated by the latter of  $\bar{E}$  or  $\bar{W}$  to transition from a high to a low. In the case of  $\bar{W}$  falling last, the output buffer will be turned on  $t_{ELQX}$  after the falling edge of  $\bar{E}$  (just as in a read cycle).

The output buffer is then turned off within  $t_{WLOZ}$  of the falling edge of  $\bar{W}$ . During this interval, it is possible to have bus contention between devices with common I/O configurations. Contention can be avoided in a carefully designed system. During a write cycle, data on the input is written into the selected cells and the output is floating.

WRITE CYCLE 1 waveform shows a write cycle terminated by  $\bar{W}$  going high. Data set-up and hold times are referenced to the rising edge of  $\bar{W}$ . When  $\bar{W}$  goes high at the end of the cycle with  $\bar{E}$  active, the output of the memory becomes active. The data from the memory will be the same as the input data unless the input data or address changes.

**RECOMMENDED AC OPERATING CONDITIONS** ( $-0^{\circ}\text{C} \leq T_A \leq 70^{\circ}\text{C}$ ) ( $V_{CC} = 5.0\text{V} \pm 10\%$ )

**WRITE CYCLE 2:  $\bar{E}$  CONTROLLED**<sup>g, h</sup>

27	$t_{WLQZ}$	$t_{WZ}$	Write Enable to Output Disable		15		20		20	ns	f, j

Note f: Measured  $\pm 200\text{mV}$  from steady state output voltage. Load capacitance is 5pF.

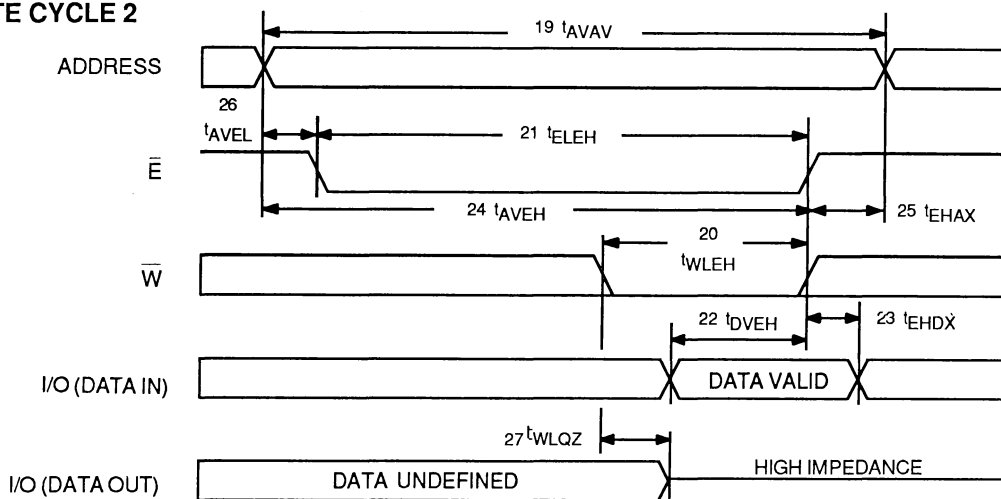

Note g:  $\bar{E}$  and  $\bar{W}$  must transition between  $V_{IH}$  to  $V_{IL}$  or  $V_{IL}$  to  $V_{IH}$  in a monotonic fashion.

Note h:  $\bar{E}$  or  $\bar{W}$  must be  $\geq V_{IH}$  during address transitions.

Note i: If  $\bar{W}$  is low when  $\bar{E}$  goes low, the outputs remain in the high impedance state.

Note j: Parameter guaranteed but not tested.

**WRITE CYCLE 2**

WRITE CYCLE 2 waveform shows a write cycle terminated by  $\bar{E}$  going high. Data set-up and hold times are referenced to the rising edge of  $\bar{E}$ . With  $\bar{E}$  high, the outputs remain in the high impedance state.

**APPLICATION**

It is imperative when designing with any very high speed memory, such as the IMS1223, that the fundamental rules in regard to memory board layout be followed to ensure proper system operation.

**POWER DISTRIBUTION**

The recommended power distribution scheme combines proper power trace layout and placement of

decoupling capacitors to maintain the operating margins of the IMS1223. The impedance in the decoupling path from the power pin (18) through the decoupling capacitor to the ground pin (9) should be kept to a minimum. The impedance of this path is determined by the series impedance of the power line inductance and the inductance and reactance of the decoupling capacitor.

Since the current transients associated with the operation of the high speed IMS1223 have very high frequency components, the line inductance is the dominating factor. To reduce the line inductance, the power trace and ground trace should be gridded or provided by separate power planes. The decoupling capacitor supplies energy

## IMS1223

for high frequency current transients and should be located as close to the devices with as short lead length as possible. The high frequency decoupling capacitor should have a value of 0.1 microfarad, and be placed between each row of devices in the array (see drawing). A larger tantalum capacitor, with a sufficient value to eliminate low frequency ripple, should be placed near the memory board edge connection where the power traces meet the backplane power distribution system. These larger capacitors provide bulk energy storage to prevent voltage drop due to the main supply being located off the memory board and at the end of a long inductive path.

The ground grid of the memory array should extend to the TTL driver peripheral circuit. This will provide a solid ground reference for the TTL drivers and prevent loss of operating margin of the drivers due to differential ground noise.

### TERMINATION

Trace lines on a memory board in the array look to TTL driver signals like low impedance, unterminated transmission lines. In order to reduce or eliminate the reflections of the TTL signals propagating down the lines, especially low going TTL signals, line termination is recommended. The termination may be either series or parallel.

The recommended technique is to use series termination. The series termination technique has the advantage of drawing no DC current and using a minimum number of components. This is accomplished by placing a series resistor in the signal line at the output of the TTL driver to dampen the reflection on the line. The resistor should be placed as close to the driver package as is practical. The line should be kept short by placing the driver-termination combination close to the memory array.

Some experimentation will have to be done to find the proper value to use for the series termination to minimize reflections, but generally a series resistor in the 10 to 33 ohm range will be required. Because each design will result in a different signal impedance, a resistor of predetermined value may not properly match the signal path impedance. The proper value of resistance should therefore be selected empirically.

**WRITE CYCLE 2**

# IMS1403

## DEVICE OPERATION

The IMS1403 has two control inputs, Chip Enable ( $\bar{E}$ ) and Write Enable ( $\bar{W}$ ), fourteen address inputs ( $A_0 - A_{13}$ ), a Data in (D) and a Data out (Q). The  $\bar{E}$  input controls device selection as well as active and standby modes. With  $\bar{E}$  low, the device is selected and the fourteen address inputs are decoded to select one bit out of 16K bits. Read and Write operations on the memory cell are controlled by  $\bar{W}$  input. With  $\bar{E}$  high, the device is deselected, the output is disabled, and power consumption is reduced to less than one-fourth of the active mode power with TTL levels and even lower with CMOS levels.

## READ CYCLE

A read cycle is defined as  $\bar{W} \geq V_{IH}$  min with  $\bar{E} \leq V_{IL}$  max. Read access time is measured from either  $\bar{E}$  going low or from valid address.

The READ CYCLE 1 waveform shows a read access that is initiated by a change in the address inputs while  $\bar{E}$  is low. The output remains active throughout READ CYCLE 1 and is valid at the specified address access time. The address inputs may change at access time as long as  $\bar{E}$  remains low, the cycle time is equal to the address access time.

The READ CYCLE 2 waveform shows a read access that is initiated by  $\bar{E}$  going low. As long as address is stable when  $\bar{E}$  goes low, valid data is at the output at the specified Chip Enable Access time. If address is not

valid when  $\bar{E}$  goes low, the timing is as specified in READ CYCLE 1. Chip Enable access time is not affected by the duration of the deselect interval.

## WRITE CYCLE

A write cycle of the IMS1403 is initiated by the latter of  $\bar{E}$  or  $\bar{W}$  to transition from a high to a low. In the case of  $\bar{W}$  falling last, the output buffer will be turned on  $t_{ELOX}$  after the falling edge of  $\bar{E}$  (just as in a read cycle). The output buffer is then turned off within  $t_{WLOZ}$  of the falling edge of  $\bar{W}$ . During this interval, it is possible to have bus contention between devices with D and Q connected together in a common I/O configuration. Contention can be avoided in a carefully designed system. During a write cycle, data on the input is written into the selected cells and the output is floating.

WRITE CYCLE 1 waveform shows a write cycle terminated by  $\bar{W}$  going high. Data set-up and hold times are referenced to the rising edge of  $\bar{W}$ . When  $\bar{W}$  goes high at the end of the cycle with  $\bar{E}$  active, the output of the memory becomes active. The data from the memory will be the same as the input data unless the input data or address changes.

WRITE CYCLE 2 waveform shows a write cycle terminated by  $\bar{E}$  going high. Data set-up and hold times are referenced to the rising edge of  $\bar{E}$ . With  $\bar{E}$  high, the outputs remain in the high impedance state.

## APPLICATION

It is imperative when designing with any very high speed memory, such as the IMS1403, that the fundamental rules in regard to memory board layout be followed to ensure proper system operation.

## POWER DISTRIBUTION

The recommended power distribution scheme combines proper power trace layout and placement of decoupling capacitors to maintain the operating margins of the IMS1403. The impedance in the decoupling path from the power pin through the decoupling capacitor, to the ground pin should be kept to a minimum. The impedance of this path is determined by the series impedance of the power line inductance and the inductance and reactance of the decoupling capacitor.

Since the current transients associated with the operation of the high speed IMS1403 have very high frequency components, the line inductance is the dominating factor.

To reduce the line inductance, the power trace and ground trace should be gridded or provided by separate power planes. The decoupling capacitor supplies energy for high frequency current transients and should be located as close to the devices with as short lead length as possible. The high frequency decoupling capacitor should have a value of  $0.1\mu\text{F}$ , and be placed between each row of devices in the array (see drawing). A larger tantalum capacitor, with a sufficient value to eliminate low frequency ripple, should be placed near the memory board edge connection where the power traces meet the backplane power distribution system. These larger capacitors provide bulk energy storage to prevent voltage drop due to the main supply being located off the memory board and at the end of a long inductive path.

The ground grid of the memory array should extend to the TTL periphery circuit. This will provide a solid ground reference for the TTL drivers and prevent loss of operating margin of the drivers due to differential ground noise.

## TERMINATION

Trace lines on a memory board in the array look to TTL driver signals like low impedance, unterminated transmission lines. In order to reduce or eliminate the reflections of the TTL signals propagating down the lines, especially low going TTL signals, line termination is recommended. The termination may be either series or parallel.

The recommended technique is to use series termination. The series termination technique has the advantage of drawing no DC current and using a minimum number of components. This is accomplished by placing a series resistor in the signal line at the output of the TTL driver to dampen the reflection on the line. The resistor should be placed as close to the driver package as is practical. The line should be kept short by placing the driver-termination combination close to the memory array.

Some experimentation will have to be done to find the proper value to use for the series termination to minimize reflections, but generally a series resistor in the 10 to 33 ohm range will be required. Because each design will result in a different signal impedance, a resistor of predetermined value may not properly match the signal path impedance. The proper value of resistance should therefore be selected empirically.

**WRITE CYCLE 2**

## IMS1423

### DEVICE OPERATION

The IMS1423 has two control inputs, Chip Enable ( $\bar{E}$ ) and Write Enable ( $\bar{W}$ ), twelve address inputs ( $A_0$ - $A_{11}$ ), and four Data I/O lines. The  $\bar{E}$  input controls device selection as well as active and standby modes. With  $\bar{E}$  low, the device is selected and the twelve address inputs are decoded to select one 4-bit word out of 4K words. Read and Write operations on the memory cell are controlled by  $\bar{W}$  input. With  $\bar{E}$  high, the device is deselected, the outputs are disabled and the power consumption is reduced to less than one-fourth of the active mode power with TTL levels and even lower with CMOS levels.

### READ CYCLE

A read cycle is defined as  $\bar{W} \geq V_{IH}$  min with  $\bar{E} \leq V_{IL}$  max. Read access time is measured from either  $\bar{E}$  going low or from valid address.

The READ CYCLE 1 waveform shows a read access that is initiated by a change in the address inputs while  $\bar{E}$  is low. The outputs remain active throughout READ CYCLE 1 and is valid at the specified address access time. The address inputs may change at access time and as long as  $\bar{E}$  remains low, the cycle time is equal to the address access time.

The READ CYCLE 2 waveform shows a read access that is initiated by  $\bar{E}$  going low. As long as address is stable when  $\bar{E}$  goes low, valid data is at the outputs at the specified Chip Enable Access time. If address is not valid when  $\bar{E}$  goes low, the timing is as specified in READ CYCLE 1. Chip Enable access time is not affected by the duration of the deselect interval.

### WRITE CYCLE

The write cycle of the IMS1423 is initiated by the latter of  $\bar{E}$  or  $\bar{W}$  to transition from a high level to a low level. In the case of  $\bar{W}$  falling last, the output buffers will be turned on  $t_{ELOX}$  after the falling edge of  $\bar{E}$  (just as in a read cycle). The output buffers are then turned off within  $t_{WLOZ}$  of the falling edge of  $\bar{W}$ . During this interval, it is possible to have bus contention between devices with common I/O configurations. Therefore input data should not be active until  $t_{WLOZ}$  to avoid bus contention.

WRITE CYCLE 1 waveform shows a write cycle terminated by  $\bar{W}$  going high. Data set-up and hold times are referenced to the rising edge of  $\bar{W}$ . When  $\bar{W}$  goes high at the end of the cycle with  $\bar{E}$  active, the outputs of the memory become active. The data from the memory will be the same as the input data unless the input data or address changes.

WRITE CYCLE 2 waveform shows a write cycle terminated by  $\bar{E}$  going high. Data set-up and hold times are referenced to the rising edge of  $\bar{E}$ . With  $\bar{E}$  high, the outputs remain in the high impedance state.

**APPLICATION**

It is imperative, when designing with any very high speed memory such as the IMS1423, that the fundamental rules in regard to memory board layout be followed to ensure proper system operation.

**POWER DISTRIBUTION**

The recommended power distribution scheme combines proper power trace layout and placement of decoupling capacitors to maintain the wide operating margins of the IMS1423. The impedance in the decoupling path from the power pin through the decoupling capacitor to the ground pin should be kept to a minimum. The impedance of this path is determined by the series impedance of the power line inductance and the inductance and reactance of the decoupling capacitor.

Since the current transients associated with the operation of the high speed IMS1423 have very high frequency components, the line inductance is the dominating factor. To reduce the line inductance, the power trace and ground trace should be gridded or provided by separate power planes. The decoupling capacitor supplies energy for high frequency current transients and should be located as close to the devices with as short lead length as possible. The high frequency decoupling capacitor should have a value of  $0.1\mu\text{F}$ , and be placed between each row of devices in the array (see drawing). A larger tantalum capacitor, with a sufficient value to eliminate low frequency ripple, should be placed near the memory board edge connection where the power traces meet the backplane power distribution system. These larger capacitors provide bulk energy storage to prevent voltage

drop due to the main supply being located off the memory board and at the end of a long inductive path.

The ground grid of the memory array should extend to the TTL periphery circuit. This will provide a solid ground reference for the TTL drivers and prevent loss of operating margin of the drivers due to differential ground noise.

**TERMINATION**

Trace lines on a memory board in the array look to TTL driver signals like low impedance, unterminated transmission lines. In order to reduce or eliminate the reflections of the TTL signals propagating down the lines, especially low going TTL signals, line termination is recommended. The termination may be either series or parallel.

The recommended technique is to use series termination. The series termination technique has the advantage of drawing no DC current and using a minimum number of components. This is accomplished by placing a series resistor in the signal line at the output of the TTL driver to dampen the reflection on the line. The resistor should be placed as close to the driver package as is practical. The line should be kept short by placing the driver-termination combination close to the memory array.

Some experimentation will have to be done to find the proper value to use for the series termination to minimize reflections, but generally a series resistor in the 10 to 33ohm range will be required. Because each design will result in a different signal impedance, a resistor of predetermined value may not properly match the signal path impedance. The proper value of resistance should therefore be selected empirically.

## DESCRIPTION

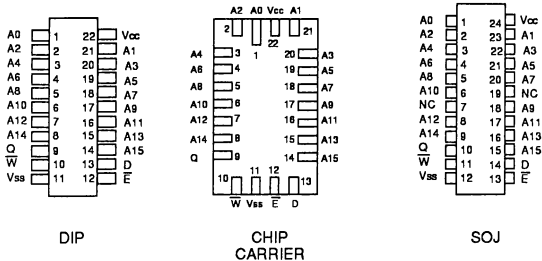

The INMOS IMS1600 is a high performance 64K x 1 CMOS Static RAM. The IMS1600 provides maximum density and speed enhancements with the additional CMOS benefits of lower power and superior reliability.

The IMS1600 features fully static operation requiring no external clocks or timing strobes, and equal address access and cycle times. Additionally, the IMS1600 provides a Chip Enable ( $\bar{E}$ ) function that can be used to place the device into a low-power standby mode.

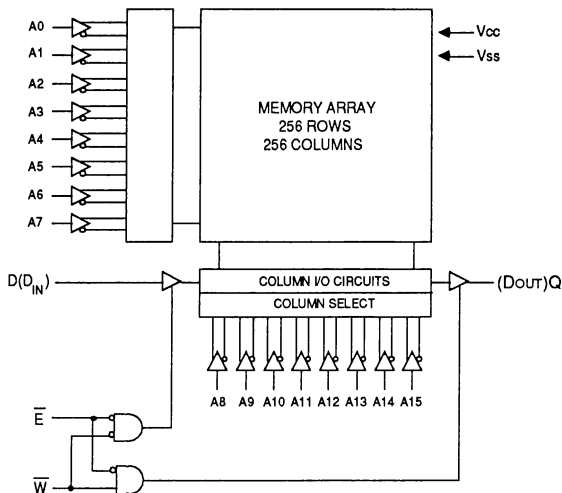

The IMS1601L is a low power version offering battery backup data retention operating from a 2 volt supply.

The IMS1600M and IMS1601LM are MIL-STD-883 versions intended for military applications.

WRITE CYCLE 2

# IMS1600/IMS1601L

## DEVICE OPERATION

The IMS1600 has two control inputs, Chip Enable ( $\overline{E}$ ) and Write Enable ( $\overline{W}$ ), 16 address inputs (A0 -A15), a data in (D) and a data out (Q).

The  $\overline{E}$  input controls device selection as well as active and standby modes. With  $\overline{E}$  low, the device is selected and the 16 address inputs are decoded to select one memory cell out of 65,536. Read and Write operations on the memory cell are controlled by the  $\overline{W}$  input. With  $\overline{E}$  high, the device is deselected, the output is disabled and the power consumption is reduced to less than one-fourth of the active mode power with TTL levels and even lower with CMOS levels.

### READ CYCLE

A read cycle is defined as  $\overline{W} \geq V_{IH\ min}$  with  $\overline{E} \leq V_{IL\ max}$ . Read access time is measured from either  $\overline{E}$  going low or from valid address.

The READ CYCLE 1 waveform shows a read access that is initiated by a change in the address inputs while  $\overline{E}$  is low. The output remains active throughout READ CYCLE 1 and is valid at the specified address access time. The address inputs may change at access time and long as  $\overline{E}$  remains low, the cycle time is equal to the address access time.

The READ CYCLE 2 waveform shows a read access that is initiated by  $\overline{E}$  going low. As long as address is stable when  $\overline{E}$  goes low, valid data is at the output at the specified Chip Enable Access time. If address is not valid when  $\overline{E}$  goes low, the timing is as specified in READ CYCLE 1. Chip Enable access time is not affected by the duration of the deselect interval.

### WRITE CYCLE

The write cycle of the IMS1600 is initiated by the latter of  $\overline{E}$  or  $\overline{W}$  to transition from a high to a low. In the case of  $\overline{W}$  falling last, the output buffer will be turned on  $t_{ELOX}$  after the falling edge of  $\overline{E}$  (just as in a read cycle). The output buffer is then turned off within  $t_{WLOZ}$  of the falling edge of  $\overline{W}$ . During this interval it is possible to have bus contention between devices with D and Q connected together in a common I/O configuration. Therefore input data should not be active until  $t_{WLOZ}$  to avoid bus contention.

WRITE CYCLE 1 waveform shows a write cycle terminated by  $\overline{W}$  going high. Data set-up and hold times are referenced to the rising edge of  $\overline{W}$ . When  $\overline{W}$  goes high at the end of the cycle with  $\overline{E}$  active, the output of the memory becomes active. The data from the memory will be the same as the input data unless the input data or address changes.

WRITE CYCLE 2 waveform shows a write cycle terminated by  $\overline{E}$  going high. Data set-up and hold times are referenced to the rising edge of  $\overline{E}$ . With  $\overline{E}$  high the output remains in the high impedance state.

## POWER DISTRIBUTION

The recommended power distribution scheme combines proper power trace layout and placement of decoupling capacitors to maintain the operating margins of the IMS1600. The impedance in the decoupling path from the power pin through the decoupling capacitor to the ground pin should be kept to a minimum. The impedance of this path is determined by the series impedance of the power line inductance and the inductance and reactance of the decoupling capacitor.

Current transients associated with the operation of any high speed device have very high frequency components, so line inductance is the dominating factor. To reduce the line inductance, the power trace and ground trace should be gridded or provided by separate power planes. The decoupling capacitor supplies energy for high frequency current transients and should be located as close to the devices with as short lead length as possible. The high frequency decoupling capacitor should have a value of 0.1 microfarad and be placed between each row of devices in the array. A larger tantalum capacitor of a sufficient value to eliminate low frequency ripple, should be placed near the memory board edge connection where the power traces meet the backplane power distribution system. These larger capacitors provide bulk energy storage to prevent voltage drop due to the main supply being located off the memory board and at the end of a long inductive path. The ground grid of the memory array should extend to the TTL driver periphery circuit area. This will provide a solid ground reference for the TTL drivers and prevent loss of operating margin of the drivers due to differential ground noise.

**TERMINATION**

Trace lines on a memory board in the array look to TTL driver signals like low impedance, unterminated transmission lines. In order to reduce or eliminate the reflections of the TTL signals propagating down the lines, especially low going TTL signals, line termination is recommended. The termination may be either series or parallel.

The recommended technique is to use series termination. The series termination technique has the advantage of drawing no DC current and using a minimum number of components. This is accomplished by placing a series resistor in the signal line at the output of the TTL driver to

dampen the reflection on the line. The resistor should be placed as close to the driver package as is practical. The line should be kept short by placing the driver-termination combination close to the memory array.

Some experimentation will have to be done to find the proper value to use for the series termination to minimize reflections, but generally a series resistor in the 10 to 33 ohm range will be required. Because each design will result in a different signal impedance, a resistor of predetermined value may not properly match the signal path impedance. The proper value of resistance should therefore be selected empirically.

**DATA RETENTION** (L version only) ( $0^{\circ}\text{C} \leq T_A \leq 70^{\circ}\text{C}$ )

SYMBOL	PARAMETER	MIN	TYP*	MAX	UNITS	NOTES
$V_{DR}$	Data Retention Voltage	2.0			volts	$V_{IN} \leq 0.2V$ or $\geq (V_{CC}-0.2V)$ $\bar{E} \geq (V_{CC}-0.2V)$

# IMS1620

## DEVICE OPERATION

The IMS1620 has two control inputs, Chip Enable (/E) and Write Enable (/W), 14 address inputs (A0 -A13), and four Data I/O pins.

The /E input controls device selection as well as active and standby modes. With /E low, the device is selected and the 14 address inputs are decoded to select one 4-bit word out of 16,384. Read and Write operations on the memory cells are controlled by the /W input. With /E high, the device is deselected, the outputs are disabled and the power consumption is reduced to less than one-fourth of the active mode power with TTL levels and even lower with CMOS levels.

### READ CYCLE

A read cycle is defined as  $/W \geq V_{IH} \text{ min}$  with  $/E \leq V_{IL} \text{ max}$ . Read access time is measured from either /E going low or from valid address.

The READ CYCLE 1 waveform shows a read access that is initiated by a change in the address inputs while /E is low. The outputs remain active throughout READ CYCLE 1 and is valid at the specified address access time. The address inputs may change at access time and long as /E remains low, the cycle time is equal to the address access time.

The READ CYCLE 2 waveform shows a read access that is initiated by /E going low. As long as address is stable when /E goes low, valid data is at the outputs at the specified Chip Enable Access time. If address is not valid when /E goes low, the timing is as specified in READ CYCLE 1. Chip Enable access time is not affected by the duration of the deselect interval.

### WRITE CYCLE

The write cycle of the IMS1620 is initiated by the latter of /E or /W to transition from a high to a low. In the case of /W falling last, the output buffers are turned on  $t_{ELOW}$  after the falling edge of /E (just as in a read cycle). The output buffers are then turned off within  $t_{WLOZ}$  of the falling edge of /W. During this interval it is possible to have bus contention between devices with common I/O configurations. Therefore input data should not be active until  $t_{WLOZ}$  to avoid bus contention.

WRITE CYCLE 1 waveform shows a write cycle terminated by /W going high. Data set-up and hold times are referenced to the rising edge of /W. When /W goes high at the end of the cycle with /E active, the output of the memory becomes active. The data from the memory will be the same as the input data unless the input data or address changes.

WRITE CYCLE 2 waveform shows a write cycle terminated by /E going high. Data set-up and hold times are referenced to the rising edge of /E. With /E high the outputs remain in the high impedance state.

## POWER DISTRIBUTION

The recommended power distribution scheme combines proper power trace layout and placement of decoupling capacitors to maintain the operating margins of the IMS1620. The impedance in the decoupling path from the power pin through the decoupling capacitor to the ground pin should be kept to a minimum. The impedance of this path is determined by the series impedance of the power line inductance and the inductance and reactance of the decoupling capacitor.

Current transients associated with the operation of any high speed device have very high frequency components, so line inductance is the dominating factor. To reduce the line inductance, the power trace and ground trace should be gridded or provided by separate power planes. The decoupling capacitor supplies energy for high frequency current transients and should be located as close to the devices with as short lead length as possible. The high frequency decoupling capacitor should have a value of 0.1 microfarad and be placed between each row of devices in the array. A larger tantalum capacitor of a sufficient value to eliminate low frequency ripple, should be placed near the memory board edge connection where the power traces meet the backplane power distribution system. These larger capacitors provide bulk energy storage to prevent voltage drop due to the main supply being located off the memory board and at the end of a long inductive path. The ground grid of the memory array should extend to the TTL driver periphery circuit area. This will provide a solid ground reference for the TTL drivers and prevent loss of operating margin of the drivers due to differential ground noise.

## TERMINATION

Trace lines on a memory board in the array look to TTL driver signals like low impedance, unterminated transmission lines. In order to reduce or eliminate the reflections of the TTL signals propagating down the lines, especially low going TTL signals, line termination is recommended. The termination may be either series or parallel.

The recommended technique is to use series termination. The series termination technique has the advantage of drawing no DC current and using a minimum number of components. This is accomplished by placing a series resistor in the signal line at the output of the TTL driver to

dampen the reflection on the line. The resistor should be placed as close to the driver package as is practical. The line should be kept short by placing the driver-termination combination close to the memory array.

Some experimentation will have to be done to find the proper value to use for the series termination to minimize reflections, but generally a series resistor in the 10 to 33 ohm range will be required. Because each design will result in a different signal impedance, a resistor of predetermined value may not properly match the signal path impedance. The proper value of resistance should therefore be selected empirically.

**WRITE CYCLE 1**

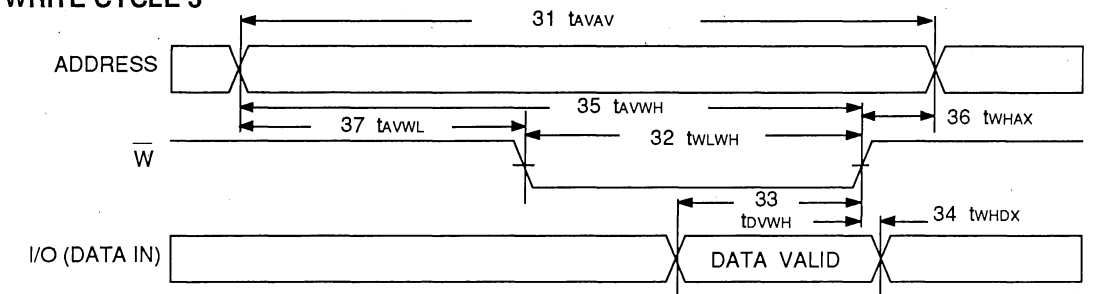

**IMS1624**

**WRITE CYCLE 2**

**WRITE CYCLE 3**

# IMS1624

## DEVICE OPERATION

The IMS1624 has three control inputs, Chip Enable (/E), Output Enable (/G) and Write Enable (/W), 14 address inputs (A0 -A13), and four Data I/O pins.

The /E input controls device selection as well as active and standby modes. With /E low, the device is selected and the 14 address inputs are decoded to select one 4-bit word out of 16,384. Read and Write operations on the memory cells are controlled by the /W and /G inputs. With /E high, the device is deselected, the outputs are disabled and the power consumption is reduced to less than one-fourth of the active mode power with TTL levels and even lower with CMOS levels.

### READ CYCLE

A read cycle is defined as  $/W \geq V_{IH}$  min with /E and /G  $\leq V_{IL}$  max. Read access time is measured from the latter of either /E or /G going low or from valid address.

The READ CYCLE 1 waveform shows a read access that is initiated by a change in the address inputs while /E and /G are low. The outputs remain active throughout READ CYCLE 1 and are valid at the specified address access time. The address inputs may change at access time and long as /E and /G remain low, the cycle time is equal to the address access time.

The READ CYCLE 2 waveform shows a read access that is initiated by the latter of /E or /G going low. As long as address is stable when /E goes low, valid data is at the outputs at the latter of specified Chip Enable Access or Output Enable Access times. If address is not valid when /E goes low, the timing is as specified in READ CYCLE 1. Chip Enable access time is not affected by the duration of the deselect interval.

Since /G controls the output buffers, /G is required to be low in order for the outputs to be active.

## WRITE CYCLE

The write cycle of the IMS1624 is initiated by the latter of /E or /W to transition from a high to a low. In the case of /W falling last, the output buffers are turned on  $t_{EOL}$  after the falling edge of /E if /G is already low (just as in a read cycle). The output buffers are then turned off within  $t_{WOL}$  of the falling edge of /W. During this interval it is possible to have bus contention between devices with common I/O configurations. Therefore input data should not be active until  $t_{WOL}$ . To avoid bus contention, the /G input can be held high throughout the write operation.

WRITE CYCLE 1 waveform shows a write cycle terminated by /W going high. Data set-up and hold times are referenced to the rising edge of /W. When /W goes high at the end of the cycle with /E active, the output of the memory becomes active (if /G is low). The data from the memory will be the same as the input data unless the input data or address changes.

WRITE CYCLE 2 waveform shows a write cycle terminated by /E going high. Data set-up and hold times are referenced to the rising edge of /E. With /E high the outputs remain in the high impedance state.

WRITE CYCLE 3 waveform shows a write cycle controlled by /W, with /G high and /E low throughout the cycle. As the outputs will not become active during this operation, maximum data bandwidth is provided by allowing very short write cycles and eliminating any bus contention considerations.

## POWER DISTRIBUTION

The recommended power distribution scheme combines proper power trace layout and placement of decoupling capacitors to maintain the operating margins of the IMS1624. The impedance in the decoupling path from the power pin through the decoupling capacitor to the ground pin should be kept to a minimum. The impedance of this path is determined by the series impedance of the power line inductance and the inductance and reactance of the decoupling capacitor.

Current transients associated with the operation of any high speed device have very high frequency components, so line inductance is the dominating factor. To reduce the line inductance, the power trace and ground trace should be gridded or provided by separate power planes. The decoupling capacitor supplies energy for high frequency current transients and should be located as close to the devices with as short lead length as possible. The high frequency decoupling capacitor should have a value of 0.1 microfarad and be placed between each row of devices in the array. A larger tantalum capacitor of a sufficient value to eliminate low frequency ripple, should be placed near the memory board edge connection where the power traces meet the backplane power distribution system. These larger capacitors provide bulk energy storage to prevent voltage drop due to the main supply being located off the memory board and at the end of a long inductive path. The ground grid of the memory array should extend to the TTL driver periphery circuit area. This

will provide a solid ground reference for the TTL drivers and prevent loss of operating margin of the drivers due to differential ground noise.

## TERMINATION

Trace lines on a memory board in the array look to TTL driver signals like low impedance, unterminated transmission lines. In order to reduce or eliminate the reflections of the TTL signals propagating down the lines, especially low going TTL signals, line termination is recommended. The termination may be either series or parallel.

The recommended technique is to use series termination. The series termination technique has the advantage of drawing no DC current and using a minimum number of components. This is accomplished by placing a series resistor in the signal line at the output of the TTL driver to dampen the reflection on the line. The resistor should be placed as close to the driver package as is practical. The line should be kept short by placing the driver-termination combination close to the memory array.

Some experimentation will have to be done to find the proper value to use for the series termination to minimize reflections, but generally a series resistor in the 10 to 33 ohm range will be required. Because each design will result in a different signal impedance, a resistor of predetermined value may not properly match the signal path impedance. The proper value of resistance should therefore be selected empirically.

# IMS1203M CMOS High Performance 4K x 1 Static RAM MIL-STD-883C

## FEATURES

- INMOS' Very High Speed CMOS
- Advanced Process - 1.6 Micron Design Rules
- Specifications guaranteed over full military temperature range (-55° C to + 125° C)
- 4K x 1 Bit Organization
- 25, 35, and 45 nsec Access Times
- Single +5V  $\pm$  10% Operation
- Power Down Function
- Fully TTL Compatible
- Separate Data Input and Output
- Three-state Output
- Standard Military Drawing version available (refer to page B-7)
- 18-Pin, 300-mil DIP (JEDEC Std.) and FP

## DESCRIPTION

The INMOS IMS1203M is a high speed CMOS 4Kx1 static RAM processed in full compliance to MIL-STD-883C. The IMS1203M provides performance enhancements with the additional CMOS benefits of lower power and superior reliability.

The IMS1203M features fully static operation requiring no external clocks or timing strobes, and equal address access and cycle times. Additionally, the IMS1203M provides a Chip Enable (/E) function that can be used to place the device into a low-power standby mode.

The IMS1203M is a VLSI static RAM intended for military temperature applications that demand superior performance and reliability.

Note j: Parameter guaranteed but not tested.

**WRITE CYCLE 2**

## IMS1203M

### DEVICE OPERATION

The IMS1203M has two control inputs, Chip Enable ( $\bar{E}$ ) and Write Enable ( $\bar{W}$ ), twelve address inputs ( $A_0$ - $A_{11}$ ), a Data In (D) and a Data Out (Q). The  $\bar{E}$  input controls device selection as well as active and standby modes. With  $\bar{E}$  low, the device is selected and the twelve address inputs are decoded to select one bit out of 4K bits. Read and Write operations on the memory cell are controlled by  $\bar{W}$  input. With  $\bar{E}$  high, the device is deselected, the output is disabled, and the power consumption is reduced to less than one-fourth of the active mode power with TTL levels and even lower with CMOS levels.

### READ CYCLE

A read cycle is defined as  $\bar{W} \geq V_{IH}$  min with  $\bar{E} \leq V_{IL}$  max. Read access time is measured from either  $\bar{E}$  going low or from valid address.

The READ CYCLE 1 waveform shows a read access that is initiated by a change in the address inputs while  $\bar{E}$  is low. The outputs remain active throughout READ CYCLE 1 and is valid at the specified address access time. The address inputs may change at access time and as long as  $\bar{E}$  remains low, the cycle time is equal to the address access time.

The READ CYCLE 2 waveform shows a read access that is initiated by  $\bar{E}$  going low. As long as address is stable when  $\bar{E}$  goes low, valid data is at the output at the specified Chip Enable Access time. If address is not valid when  $\bar{E}$  goes low, the timing is as specified in READ CYCLE 1. Chip Enable access time is not affected by the duration of the deselect interval.

### WRITE CYCLE

The write cycle of the IMS1203M is initiated by the latter of  $\bar{E}$  or  $\bar{W}$  to transition from a high to low. In the case of  $\bar{W}$  falling last, the output buffer will be turned on  $t_{ELQX}$  after the falling edge of  $\bar{E}$  (just as in a read cycle). The output buffer is then turned off within  $t_{WLQZ}$  of the falling edge of  $\bar{W}$ . During this interval, it is possible to have bus contention between devices with D and Q connected together in a common I/O configuration. Contention can be avoided in a carefully designed system. During a write cycle, data on the input is written into the selected cells and the output is floating.

WRITE CYCLE 1 waveform shows a write cycle terminated by  $\bar{W}$  going high. Data set-up and hold times are referenced to the rising edge of  $\bar{W}$ . When  $\bar{W}$  goes high at the end of the cycle with  $\bar{E}$  active, the output of the memory becomes active. The data from the memory will be the same as the input data unless the input data or address changes.

WRITE CYCLE 2 waveform shows a write cycle terminated by  $\bar{E}$  going high. Data set-up and hold times are referenced to the rising edge of  $\bar{E}$ . With  $\bar{E}$  high, the outputs remain in the high impedance state.

### APPLICATION

It is imperative when designing with any very high speed memory, such as the IMS1203M, that the fundamental rules in regard to memory board layout be followed to ensure proper system operation.

### TERMINATION

Trace lines on a memory board in the array look to TTL driver signals like low impedance, unterminated transmission lines. In order to reduce or eliminate the reflections of the TTL signals propagating down the lines, especially low going TTL signals, line termination is recommended. The termination may be either series or parallel.

The recommended technique is to use series termination. The series termination technique has the advantage of drawing no DC current and using a minimum number of components. This is accomplished by placing a series resistor in the signal line at the output of the TTL driver to dampen the reflection on the line. The resistor should be placed as close to the driver package as is practical. The line should be kept short by placing the driver-termination combination close to the memory array.

Some experimentation will have to be done to find the proper value to use for the series termination to minimize reflections, but generally a series resistor in the 10 to 33 ohm range will be required. Because each design will result in a different signal impedance, a resistor of predetermined value may not properly match the signal path impedance. The proper value of resistance should therefore be selected empirically.

## POWER DISTRIBUTION

The recommended power distribution scheme combines proper power trace layout and placement of decoupling capacitors to maintain the operating margins of the IMS1203M. The impedance in the decoupling path from the power pin through the decoupling capacitor to the ground pin should be kept to a minimum. The impedance of this path is determined by the series impedance of the power line inductance and the inductance and reactance of the decoupling capacitor.

Since the current transients associated with the operation of the high speed IMS1203M have very high frequency components, the line inductance is the dominating factor. To reduce the line inductance, the power trace and ground trace should be gridded or provided by separate power planes. The decoupling capacitor supplies energy for high frequency current transients and should be located as close to the devices with as short lead length as possible. The high frequency decoupling capacitor should have a value of 0.1 microfarad, and be placed between each row of devices in the array (see drawing). A larger tantalum capacitor, with a sufficient value to eliminate low frequency ripple, should be placed near the memory board edge connection where the power traces meet the backplane power distribution system. These larger capacitors provide bulk energy storage to prevent voltage drop due to the main supply being located off the memory board and at the end of a long inductive path.

The ground grid of the memory array should extend to the TTL driver periphery circuit. This will provide a solid ground reference for the TTL drivers and prevent loss of operating margin of the drivers due to differential ground noise.

**WRITE CYCLE 2**

# IMS1223M

## DEVICE OPERATION

The IMS1223M has two control inputs, Chip Enable ( $\bar{E}$ ) and Write Enable ( $\bar{W}$ ), ten address inputs ( $A_0-A_9$ ), and four Data I/O lines. The  $\bar{E}$  input controls device selection as well as active and standby modes. With  $\bar{E}$  low, the device is selected and the ten address inputs are decoded to select one four-bit word out of 1K words. Read and Write operations on the memory cell are controlled by  $\bar{W}$  input. With  $\bar{E}$  high, the device is deselected, the output is disabled and the power consumption is reduced to less than one-fourth of the active mode power with TTL levels and even lower with CMOS levels.

## READ CYCLE

A read cycle is defined as  $\bar{W} \geq V_{IH}$  min with  $\bar{E} \leq V_{IL}$  max. Read access time is measured from either  $\bar{E}$  going low or from valid address.

The READ CYCLE 1 waveform shows a read access that is initiated by a change in the address inputs while  $\bar{E}$  is low. The outputs remain active throughout READ CYCLE 1 and are valid at the specified address access time. The address inputs may change at access time and as long as  $\bar{E}$  remains low, the cycle time is equal to the address access time.

The READ CYCLE 2 waveform shows a read access that is initiated by  $\bar{E}$  going low. As long as address is stable when  $\bar{E}$  goes low, valid data is at the outputs at the specified Chip Enable Access time. If address is not valid when  $\bar{E}$  goes low, the timing is as specified in READ CYCLE 1. Chip Enable access time is not affected by the duration of the deselect interval.

## WRITE CYCLE

The write cycle of the IMS1223M is initiated by the latter of  $\bar{E}$  or  $\bar{W}$  to transition from a high to a low. In the case of  $\bar{W}$  falling last, the output buffers will be turned on at  $t_{ELQX}$  after the falling edge of  $\bar{E}$  (just as in a read cycle). The output buffers are then turned off within  $t_{WLQZ}$  of the falling edge of  $\bar{W}$ . During this interval, it is possible to have bus contention between devices with common I/O configurations. To avoid bus contention, input data should not become active on the I/O bus until  $t_{WLQZ}$ .

WRITE CYCLE 1 waveform shows a write cycle terminated by  $\bar{W}$  going high. Data set-up and hold times are referenced to the rising edge of  $\bar{W}$ . When  $\bar{W}$  goes high at the end of the cycle with  $\bar{E}$  active, the output of the memory becomes active. The data from the memory will be the same as the input data unless the input data or address changes.

WRITE CYCLE 2 waveform shows a write cycle terminated by  $\bar{E}$  going high. Data set-up and hold times are referenced to the rising edge of  $\bar{E}$ . With  $\bar{E}$  high the outputs remain in the high impedance state.

## APPLICATION

It is imperative when designing with any very high speed memory, such as the IMS1223M, that the fundamental rules in regard to memory board layout be followed to ensure proper system operation.

## TERMINATION

Trace lines on a memory board in the array look to TTL driver signals like low impedance, unterminated transmission lines. In order to reduce or eliminate the reflections of the TTL signals propagating down the lines, especially low going TTL signals, line termination is recommended. The termination may be either series or parallel.

The recommended technique is to use series termination. The series termination technique has the advantage of drawing no DC current and using a minimum number of components. This is accomplished by placing a series resistor in the signal line at the output of the TTL driver to dampen the reflection on the line. The resistor should be placed as close to the driver package as is practical. The line should be kept short by placing the driver-termination combination close to the memory array.

Some experimentation will have to be done to find the proper value to use for the series termination to minimize reflections, but generally a series resistor in the 10 to 33 ohm range will be required. Because each design will result in a different signal impedance, a resistor of predetermined value may not properly match the signal path impedance. The proper value of resistance should therefore be selected empirically.

**POWER DISTRIBUTION**

The recommended power distribution scheme combines proper power trace layout and placement of decoupling capacitors to maintain the operating margins of the IMS1223M. The impedance in the decoupling path from the power pin through the decoupling capacitor to the ground pin should be kept to a minimum. The impedance of this path is determined by the series impedance of the power line inductance and the inductance and reactance of the decoupling capacitor.

Since the current transients associated with the operation of the high speed IMS1223M have very high frequency components, the line inductance is the dominating factor. To reduce the line inductance, the power trace and ground trace should be gridded or provided by separate power planes. The decoupling capacitor supplies energy for high frequency current transients and should be located as close to the devices with as short lead length as possible. The high frequency decoupling capacitor should have a value of 0.1 microfarad, and be placed between each row of devices in the array (see drawing). A larger tantalum capacitor, with a sufficient value to eliminate low frequency ripple, should be placed near the memory board edge connection where the power traces meet the backplane power distribution system. These larger capacitors provide bulk energy storage to prevent voltage drop due to the main supply being located off the memory board and at the end of a long inductive path.

The ground grid of the memory array should extend to the TTL driver periphery circuit. This will provide a solid ground reference for the TTL drivers and prevent loss of operating margin of the drivers due to differential ground noise.

## High Performance 16K Static RAM MIL-STD-883C

### FEATURES

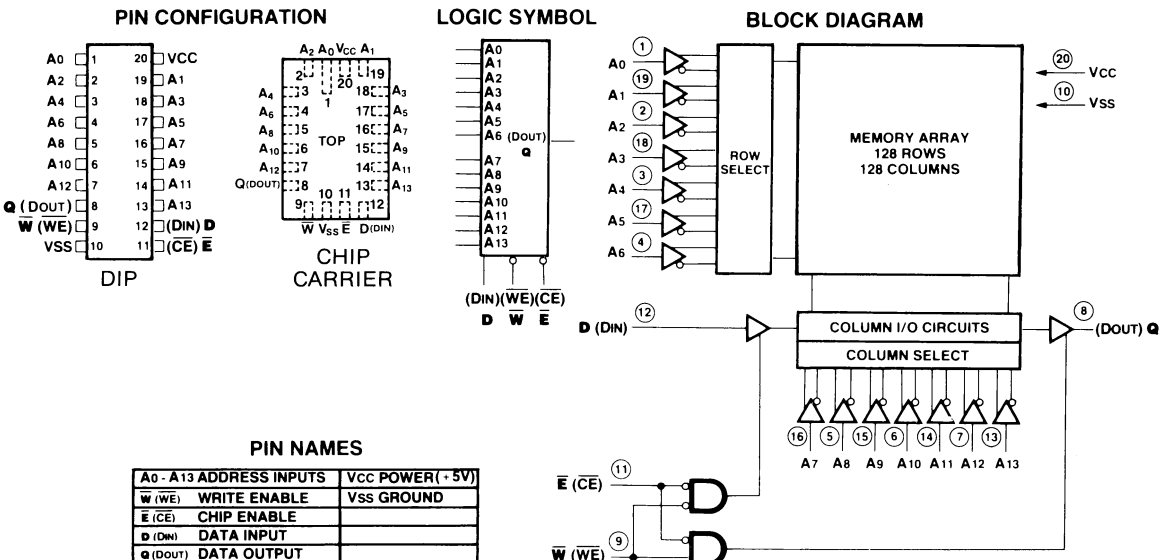

- Full Military Temperature Operating Range (-55°C to +125°C)
- MIL-STD-883C Processing
- 45, 55 and 70 nsec Access Times
- Fully TTL Compatible
- Separate Data Input & Output
- Three-state Output
- Power Down Function
- Single +5V ± 10% Operation
- 20-Pin, 300-mil DIP (JEDEC Std.)
- 20-Pin Ceramic LCC (JEDEC Std.)

### DESCRIPTION

The INMOS IMS1400M is a high performance 16Kx1 Static RAM processed in full compliance to MIL-STD-883C with access times as fast as 45nsec and a maximum power consumption of 660mW. These characteristics are made possible by the combination of innovative circuit design and INMOS' proprietary NMOS technology.

The IMS1400M features fully static operation requiring no external clocks or timing strobes with equal access and cycle times. Additionally, the IMS1400M provides a Chip Enable (/E) function that can be used to place the device into a low-power standby mode reducing consumption to less than 165mW.

The IMS1400M is a high speed VLSI RAM intended for military applications which demand superior performance and reliability.

**WRITE CYCLE 2**

# IMS1400M

## DEVICE OPERATION

The IMS1400M has two control inputs: Chip Enable ( $\overline{E}$ ) and Write Enable ( $\overline{W}$ ), 14 address inputs, a data in ( $D_{IN}$ ) and a data out ( $D_{OUT}$ ).

When  $V_{CC}$  is first applied to pin 20, a circuit associated with the  $\overline{E}$  input forces the device into the lower power standby mode regardless of the state of the  $\overline{E}$  input. After  $V_{CC}$  is applied for 2ms the  $\overline{E}$  input controls device selection as well as active and standby modes.

With  $\overline{E}$  low, the device is selected and the 14 address inputs are decoded to select one memory cell out of 16,385. READ and WRITE operations on the memory cell are controlled by  $\overline{W}$  input. With  $\overline{E}$  high, the device is deselected, the output is disabled, and the power consumption is reduced to less than  $\frac{1}{4}$  of the active mode power.

## READ CYCLE

A read cycle is defined as  $\overline{W} \geq V_{IH}$  min with  $\overline{E} \leq V_{IL}$  max. Read access time is measured from either  $\overline{E}$  going low or from valid address.

The READ CYCLE 1 waveform on page 3 shows a read access that is initiated by a change in the address inputs while  $\overline{E}$  is low. The output remains active throughout a READ CYCLE 1 and is valid at the specified address access time. As long as  $\overline{E}$  remains low, the cycle time is equal to the address access time.

The READ CYCLE 2 waveform on page 3 shows a read access that is initiated by  $\overline{E}$  going low. As long as address is stable within 5ns after  $\overline{E}$  goes low, valid data is at the output at the specified Chip Enable access time. If address is not valid within 5ns after  $\overline{E}$  goes low, the timing is as specified in the READ CYCLE 1. Chip Enable access time is not affected by the duration of the deselect interval.

## WRITE CYCLE

A write cycle is initiated by the latter of  $\overline{W}$  or  $\overline{E}$  going low, and terminated by  $\overline{W}$  (WRITE CYCLE 1) or  $\overline{E}$  (WRITE CYCLE 2) going high. During the write cycle, data on the input ( $D_{IN}$ ) is written into the selected cell, and the output ( $D_{OUT}$ ) is in high impedance.

If a write cycle is initiated by  $\overline{W}$  going low, the address must be stable for the WRITE CYCLE 1 set-up time. If a write cycle is initiated by  $\overline{E}$  going low, the address must be held stable for the entire write cycle. After  $\overline{W}$  or  $\overline{E}$  goes high to terminate the cycle, addresses may change. If these address set-up and hold times are not met, contents of other cells may be altered in unpredictable ways.

WRITE CYCLE 1 waveform on page 4 shows a write cycle terminated by  $\overline{W}$  going high.  $D_{IN}$  set-up and hold times are referenced to the rising edge of  $\overline{W}$ . With  $\overline{W}$  high,  $D_{OUT}$  becomes active.

WRITE CYCLE 2 waveform on page 5 shows a write cycle terminated by  $\overline{E}$  going high.  $D_{IN}$  set-up and hold times are referenced to the rising edge of  $\overline{E}$ . With  $\overline{E}$  high,  $D_{OUT}$  remains in the high impedance state.

## APPLICATION

To ensure proper operation of the extended temperature IMS1400M in a system environment, it is recommended that the following guidelines on board layout and power distribution be followed.

## POWER DISTRIBUTION

The recommended power distribution scheme combines proper power trace layout and placement of decoupling capacitors. The impedance in the decoupling path from the power pin (20) through the decoupling capacitor, to the ground pin (10) should be kept to a minimum. The impedance of this path is determined by the series impedance of the power line inductance and the inductance and reactance of the decoupling capacitor.

To reduce the power line impedance, it is recommended that the power trace and ground trace be gridded or provided by separate power planes. The high frequency decoupling capacitor should have a value of  $0.1\mu\text{F}$ , and be placed between the rows of memory devices in the array (see Figure 2). A larger tantalum capacitor with a value between  $22\mu\text{F}$  and  $47\mu\text{F}$  should be placed near the memory board edge connection where the power traces meet the backplane power distribution system. These large capacitors provide bulk energy storage to prevent voltage drop due to the main supply being located off the memory board and at the end of a long inductive path.

Also, to prevent loss of signal margins due to differential ground noise, the ground grid of the memory array should be extended to the TTL drivers in the peripheral circuitry.

**TERMINATION**

Trace lines on a memory board in the array look to TTL driver, signals like low impedance, unterminated transmission lines. In order to reduce or eliminate the reflections of the TTL signals, line termination is recommended. The termination may be either parallel or series but the series termination technique has the advantages of drawing no DC current and using a minimum of components. The recommended technique is to use series termination.

A series resistor in the signal line at the output of the TTL driver to match the source impedance of the TTL driver to the signal line will dampen the reflections on the line. The line should be kept short with the driver-termination combination close to the memory array.

Some experimentation will have to be done to find the proper value to use for the series termination to minimize reflections, but generally a series resistor in the 10Ω to 30Ω range will be required.

The use of proper power distribution techniques, including adequate use of decoupling capacitors, along with proper termination of TTL driver outputs, are some of the most important, yet basic rules to be followed.

The rules are intended to maintain the operating margins of all devices on the memory board by providing a quiet environment relatively free of noise spikes and signal reflections.

### High Performance 16K x 1 Static RAM MIL-STD-883C

#### FEATURES

- INMOS' Very High Speed CMOS
- Advanced Process - 1.6 Micron Design Rules
- Specifications guaranteed over full military temperature range (-55° C to +125° C)
- 16K x 1 Bit Organization
- 35, 45, 55 nsec Access Times
- Fully TTL Compatible
- Separate Data Input & Output
- Three-state Output
- Single +5V ± 10% Operation
- Power Down Function
- Pin Compatible with IMS1400M
- Standard Military Drawing version available
- 20-Pin, 300-mil DIP & LCC (JEDEC Std.)
- Battery Backup Operation - 2V Data Retention (L version only)

#### DESCRIPTION

The INMOS IMS1403M is a high speed 16K x 1 CMOS static RAM processed in full compliance to MIL-STD-883C. The IMS1403M provides maximum density and performance enhancements with the additional CMOS benefits of lower power and superior reliability.

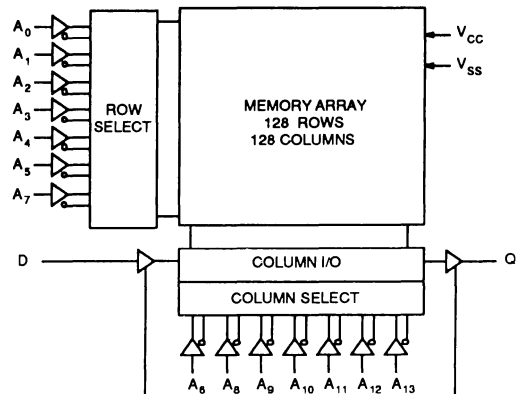

The IMS1403M features fully static operation requiring no external clocks or timing strobes, and equal address access and cycle times. Additionally, the IMS1403M provides a Chip Enable (/E) function that can be used to place the device into a low-power standby mode.

The IMS1403LM is a low power version offering battery backup data retention operating from a 2 volt supply.

## ABSOLUTE MAXIMUM RATINGS\*

Voltage on any pin relative to  $V_{SS}$ .....-2.0 to 7.0V  
 Voltage on Q.....-1.0 to ( $V_{CC}+ .5$ )V  
 Temperature Under Bias.....-55° C to 125°C  
 Storage Temperature .....-65° C to 150°C  
 Power Dissipation.....1W  
 DC Output Current.....25mA

(One Second Duration)

\*Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

## DC OPERATING CONDITIONS

SYMBOL	PARAMETER	MIN	TYP	MAX	UNITS	NOTES
$V_{CC}$	Supply Voltage	4.5	5.0	5.5	V	
$V_{SS}$	Supply Voltage	0	0	0	V	
$V_{IH}$	Input Logic "1" Voltage	2.0		$V_{CC}+.5$	V	All inputs
$V_{IL}$	Input Logic "0" Voltage	-1.0*		0.8	V	All inputs
$T_A$	Ambient Operating Temperature	-55	25	125	°C	400 linear ft/min air flow

\*  $V_{IL}$  Min = -3.0V for pulse width <20ns, note b.

## DC ELECTRICAL CHARACTERISTICS (-55°C ≤ $T_A$ ≤ 125°C) ( $V_{CC} = 5.0V \pm 10%$ )<sup>a</sup>

SYMBOL	PARAMETER	MIN	MAX	UNITS	NOTES
$I_{CC1}$	Average $V_{CC}$ Power Supply Current		75	mA	$t_{AVAV} = t_{AVAV}$ (min)
$I_{CC2}$	$V_{CC}$ Power Supply Current (Standby, Stable TTL Input Levels)		15	mA	$\bar{E} \geq V_{IH}$ All other inputs at $V_{IN} \leq V_{IL}$ or $\geq V_{IH}$
$I_{CC3}$	$V_{CC}$ Power Supply Current (Standby, Stable CMOS Input Levels)		5	mA	$\bar{E} \geq (V_{CC} - 0.2)$ All other inputs at $V_{IN} \leq 0.2$ or $\geq (V_{CC} - 0.2V)$
$I_{CC4}$	$V_{CC}$ Power Supply Current (Standby, Cycling CMOS Input Levels)		10	mA	$\bar{E} \geq (V_{CC} - 0.2)$ Inputs cycling at $V_{IN} \leq 0.2$ or $\geq (V_{CC} - 0.2V)$
$I_{ILK}$	Input Leakage Current (Any Input)		±5	µA	$V_{CC} = \max$ $V_{IN} = V_{SS}$ to $V_{CC}$
$I_{OLK}$	Off State Output Leakage Current		±10	µA	$V_{CC} = \max$ $V_{IN} = V_{SS}$ to $V_{CC}$
$V_{OH}$	Output Logic "1" Voltage	2.4		V	$I_{OH} = -4mA$
$V_{OL}$	Output Logic "0" Voltage		0.4	V	$I_{OL} = 16mA$

Note a:  $I_{CC}$  is dependent on output loading and cycle rate, the specified values are obtained with the output unloaded.

WRITE CYCLE 2

# IMS1403M/1403LM

## DEVICE OPERATION

The IMS1403M has two control inputs, Chip Enable (/E) and Write Enable (/W), 14 address inputs (A0 -A13), a Data In (D) and a Data Out (Q). The /E input controls device selection as well as active and standby modes. With /E low, the device is selected and the 14 address inputs are decoded to select one bit out of 16K bits. Read and Write operations on the memory cell are controlled by the /W input. With /E high, the device is deselected, the outputs are disabled and the power consumption is reduced to less than one-fourth of the active mode power with TTL levels and even lower with CMOS levels.

### READ CYCLE

A read cycle is defined as /W  $\geq$  V<sub>IH</sub> min with /E  $\leq$  V<sub>IL</sub> max. Read access time is measured from either /E going low or from valid address.

The READ CYCLE 1 waveform shows a read access that is initiated by a change in the address inputs while /E is low. The output remains active throughout READ CYCLE 1 and is valid at the specified address access time. The address inputs may change at access time and long as /E remains low, the cycle time is equal to the address access time.

The READ CYCLE 2 waveform shows a read access that is initiated by /E going low. As long as address is stable when /E goes low, valid data is at the output at the specified Chip Enable Access time. If address is not valid when /E goes low, the timing is as specified in READ CYCLE 1. Chip Enable access time is not affected by the duration of the deselect interval.

## WRITE CYCLE

The write cycle of the IMS1403M is initiated by the latter of /E or /W to transition from a high to a low. In the case of /W falling last, the output buffer will be turned on t<sub>ELQX</sub> after the falling edge of /E (just as in a read cycle). The output buffer is then turned off within t<sub>WLQZ</sub> of the falling edge of /W. During this interval, it is possible to have bus contention between devices with D and Q connected together in a common I/O configuration. Contention can be avoided in a carefully designed system. During a write cycle, data on the input is written into the selected cells and the output is floating.

WRITE CYCLE 1 waveform shows a write cycle terminated by /W going high. Data set-up and hold times are referenced to the rising edge of /W. When /W goes high at the end of the cycle with /E active, the output of the memory becomes active. The data from the memory will be the same as the input data unless the input data or address changes.

WRITE CYCLE 2 waveform shows a write cycle terminated by /E going high. Data set-up and hold times are referenced to the rising edge of /E. With /E high the outputs remain in the high impedance state.

### APPLICATION

It is imperative when designing with any very high speed memory, such as the IMS1403M, that the fundamental rules in regard to memory board layout be followed to ensure proper system operation.

## DATA RETENTION (L version only) (-55°C $\leq$ T<sub>A</sub> $\leq$ 125°C)

SYMBOL	PARAMETER	MIN	TYP*	MAX	UNITS	NOTES
V <sub>DR</sub>	Data Retention Voltage	2.0			volts	V <sub>IN</sub> $\leq$ 0.2V or $\geq$ (V <sub>CC</sub> - 0.2V) $\bar{E} \geq$ (V <sub>CC</sub> - 0.2V)
I <sub>CCDR1</sub>	Data Retention Current		3	400	$\mu$ A	V <sub>CC</sub> = 3.0 volts
I <sub>CCDR2</sub>	Data Retention Current		2	250	$\mu$ A	V <sub>CC</sub> = 2.0 volts
t <sub>EHVCCL</sub>	Deselect Time (t <sub>CDR</sub> )	0			ns	j, k
t <sub>VCHEL</sub>	Recovery Time (t <sub>R</sub> )	t <sub>RC</sub>			ns	(t <sub>RC</sub> = Read Cycle Time)

\*Typical data retention parameters at 25°C.

Note j: Parameter guaranteed but not tested.

Note k: Supply recovery rate should not exceed 100mV per  $\mu$ S from V<sub>DR</sub> to V<sub>CC</sub> min.

## LOW V<sub>CC</sub> DATA RETENTION

**POWER DISTRIBUTION**

The recommended power distribution scheme combines proper power trace layout and placement of decoupling capacitors to maintain the operating margins of the IMS1403M. The impedance in the decoupling path from the power pin through the decoupling capacitor to the ground pin should be kept to a minimum. The impedance of this path is determined by the series impedance of the power line inductance and the inductance and reactance of the decoupling capacitor.

Since the current transients associated with the operation of the high speed IMS1403M have very high frequency components, the line inductance is the dominating factor. To reduce the line inductance, the power trace and ground trace should be gridded or provided by separate power planes. The decoupling capacitor supplies energy for high frequency current transients and should be located as close to the devices with as short lead length as possible. The high frequency decoupling capacitor should have a value of 0.1 microfarad, and be placed between each row of devices in the array (see drawing). A larger tantalum capacitor, with a sufficient value to eliminate low frequency ripple, should be placed near the memory board edge connection where the power traces meet the backplane power distribution system. These larger capacitors provide bulk energy storage to prevent voltage drop due to the main supply being located off the memory board and at the end of a long inductive path.

The ground grid of the memory array should extend to the TTL periphery circuit. This will provide a solid ground reference for the TTL drivers and prevent loss of operating margin of the drivers due to differential ground noise.

**TERMINATION**

Trace lines on a memory board in the array look to TTL driver signals like low impedance, unterminated transmission lines. In order to reduce or eliminate the reflections of the TTL signals propagating down the lines, especially low going TTL signals, line termination is recommended. The termination may be either series or parallel.

The recommended technique is to use series termination. The series termination technique has the advantage of drawing no DC current and using a minimum number of components. This is accomplished by placing a series resistor in the signal line at the output of the TTL driver to dampen the reflection on the line. The resistor should be placed as close to the driver package as is practical. The line should be kept short by placing the driver-termination combination close to the memory array.

Some experimentation will have to be done to find the proper value to use for the series termination to minimize reflections, but generally a series resistor in the 10 to 33 ohm range will be required. Because each design will result in a different signal impedance, a resistor of predetermined value may not properly match the signal path impedance. The proper value of resistance should therefore be selected empirically.

## High Performance 4Kx4 Static RAM MIL-STD-883C

### FEATURES

- Full Military Temperature Operating Range (-55° C to + 125° C)
- MIL-STD-883C Processing
- 4Kx4 Bit Organisation
- 55 and 70 nsec Access Times
- Fully TTL Compatible
- Common Data Input and Output
- Three-state Output
- Power Down Function
- Single +5V ± 10% Operation
- 20-Pin, 300-mil DIP (JEDEC Std.)
- 20-Pin Ceramic LCC (JEDEC Std.)

### DESCRIPTION

The INMOS IMS1420M is a high performance 4Kx4 Static RAM processed in full compliance to MIL-STD-883C with access times of 55ns and 70ns and a maximum power consumption of 660mW. These characteristics are made possible by the combination of innovative circuit design and INMOS' proprietary NMOS technology.

The IMS1420M features fully static operation requiring no external clocks or timing strobes with equal access and cycle times. Additionally, the IMS1420M provides a Chip Enable ( $\bar{E}$ ) function that can be used to place the device into a low-power standby mode reducing consumption to less than 165mW.

The IMS1420M is a high speed VLSI RAM intended for military applications which demand high performance and reliability.

Note h:  $\bar{E}$  or  $\bar{W}$  must be  $\geq V_{IH}$  during address transitions.

**WRITE CYCLE 2**

# IMS1420M

## DEVICE OPERATION

The IMS1420M has two control inputs, Chip Enable ( $\bar{E}$ ) and Write Enable ( $\bar{W}$ ), twelve address inputs, and four Data I/O lines.

When  $V_{CC}$  is first applied to pin 20, a circuit associated with the  $\bar{E}$  input forces the device into the lower power standby mode regardless of the state of the  $\bar{E}$  input. After  $V_{CC}$  is applied for 2ms the  $\bar{E}$  input controls device selection as well as active and standby modes.

With  $\bar{E}$  low, the device is selected and the twelve address inputs are decoded to select one 4-bit word out of 4096. READ and WRITE operations on the memory cell are controlled by  $\bar{W}$  input. With  $\bar{E}$  high, the device is deselected, the output is disabled, and the power consumption is reduced to less than one-third of the active mode power.

## READ CYCLE

A read cycle is defined as  $\bar{W} \geq V_{IH}$  min with  $\bar{E} \leq V_{IL}$  max. Read access time is measured from either  $\bar{E}$  going low or from valid address.

The READ CYCLE 1 waveform on page 3 shows a read access that is initiated by a change in the address inputs while  $\bar{E}$  is low. The output remains active throughout READ CYCLE 1 and is valid at the specified address access time. The address inputs may change at access time and the output remains valid for a minimum of 3ns. As long as  $\bar{E}$  remains low, the cycle time is equal to the address access time.

The READ CYCLE 2 waveform on page 3 shows a read access that is initiated by  $\bar{E}$  going low. As long as address is stable within 5ns after  $\bar{E}$  goes low, valid data is at the output at the specified Chip Enable access time. If address is not valid within 5ns after  $\bar{E}$  goes low, the timing is as specified in the READ CYCLE 1. Chip Enable access time is not affected by the duration of the deselect interval.

## WRITE CYCLE

A write cycle is initiated by the latter of  $\bar{W}$  or  $\bar{E}$  going low, and terminated by  $\bar{W}$  (WRITE CYCLE 1) or  $\bar{E}$  (WRITE CYCLE 2) going high. During the write cycle, data on the inputs is written into the selected cells, and the outputs are floating.

If a write cycle is initiated by  $\bar{W}$  going low, the address must be stable for the WRITE CYCLE 1 set-up time. If a write cycle is initiated by  $\bar{E}$  going low, the address need not be stable until a maximum of 5ns after  $\bar{E}$  goes low. The address must be held stable for the entire write cycle. After  $\bar{W}$  or  $\bar{E}$  goes high to terminate the write cycle, addresses may change. If these address set-up and hold times are not met, contents of other cells may be altered in unpredictable ways.

WRITE CYCLE 1 waveform on page 4 shows a write cycle terminated by  $\bar{W}$  going high.  $D_{IN}$  set-up and hold times are referenced to the rising edge of  $\bar{W}$ . With  $\bar{W}$  high, the outputs become active. When  $\bar{W}$  goes high at the end of a write cycle and the outputs of the memory go active, the data from the memory will be the same as the data just written into the memory. Thus, no data bus contention will occur.

WRITE CYCLE 2 waveform on page 5 shows a write cycle terminated by  $\bar{E}$  going high. Data set-up and hold times are referenced to the rising edge of  $\bar{E}$ . With  $\bar{E}$  high, the outputs remain in the high impedance state.

## APPLICATION

Fundamental rules in regard to memory board layout should be followed to ensure maximum benefit from the features offered by the IMS1420M Static RAM.

## POWER DISTRIBUTION

The recommended power distribution scheme combines proper power trace layout and placement of decoupling capacitors to maintain the operating margins of the IMS1420M. The impedance in the decoupling path from the power pin (20) through the decoupling capacitor, to the ground pin (10) should be kept to a minimum. The impedance of this path is determined by the series impedance of the power line inductance and the inductance and reactance of the decoupling capacitor.

Since the current transients associated with the operation of the high speed IMS1420M are high frequency, the line inductance is the dominating factor. To reduce the line inductance, the power trace and ground trace should be gridded or provided by separate power planes. The decoupling capacitor acts as a low impedance power supply located near the memory device. The high frequency decoupling capacitor should have a value of 0.1 $\mu$ F, and be placed between the rows of memory devices in the array (see drawing). A larger tantalum capacitor with a value between 22 $\mu$ F and 47 $\mu$ F should be placed near the memory board edge connection where the power traces meet the backplane power distribution system. These larger capacitors provide bulk energy storage to prevent voltage drop due to the main supply being located off the memory board and at the end of a long inductive path.

The ground grid of the memory array should extend to the TTL driver periphery circuit. This will provide a solid ground reference for the TTL drivers and prevent loss of operating margin of the drivers due to differential ground noise.

**VCC, VSS GRID SHOWING  
DECOUPLING CAPACITORS**

**TERMINATION**

Trace lines on a memory board in the array look to TTL driver signals like low impedance, unterminated transmission lines. In order to reduce or eliminate the reflections of the TTL signals propagating down the lines, especially low going TTL signals, line termination is recommended. The termination may be either series or parallel.

The recommended technique is to use series termination. The series termination technique has the advantage of drawing no DC current and using a minimum of components. This is accomplished by placing a series resistor in the signal line at the output of the TTL driver to dampen the reflection on the line. The line should be kept short by placing the driver-termination combination close to the memory array.

Some experimentation will have to be done to find the proper value to use for the series termination to minimize reflections, but generally a series resistor in the 10 $\Omega$  to 30 $\Omega$  range will be required.

Proper power distribution techniques, including adequate use of decoupling capacitors, and proper termination of TTL drive outputs, are some of the most important, yet basic guidelines that need to be followed when designing and building a memory board. The guidelines are intended to maintain the operating margins of all devices on the memory board by providing a quiet environment free of noise spikes and signal reflections.

### MIL-STD-883C

#### FEATURES

- INMOS' Very High Speed CMOS
- Advanced Process - 1.6 Micron Design Rules
- Specifications guaranteed over full military temperature range (-55° C to + 125° C)
- 4K x 4 Bit Organization
- 35, 45, and 55 nsec Access Times
- Single +5V ± 10% Operation
- Power Down Function for Low Standby Power
- Fully TTL Compatible
- Common Data Input and Output
- Three-state Output
- Standard Military Drawing version available (refer to page B-7)
- 20-Pin DIP, LCC (JEDEC Std.) and FP
- Pin Compatible with IMS1420M

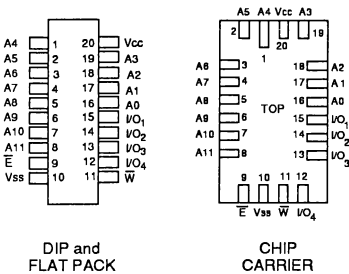

#### DESCRIPTION

The INMOS IMS1423M is a high speed 4K x 4 CMOS static RAM processed in full compliance to MIL-STD-883C. The IMS1423M provides maximum density and performance enhancements to existing 16K applications.

The IMS1423M features fully static operation requiring no external clocks or timing strobes, and equal address access and cycle times. Additionally, the IMS1423M provides a Chip Enable (/E) function that can be used to place the device into a low-power standby mode.

The IMS1423M is a VLSI static RAM intended for military applications that demand high performance and superior reliability.

Note j: Parameter guaranteed but not tested.

WRITE CYCLE 2

# IMS1423M

## DEVICE OPERATION

The IMS1423M has two control inputs, Chip Enable (/E) and Write Enable (/W), 12 address inputs (A0 -A11), and four Data I/O lines. The /E input controls device selection as well as active and standby modes. With /E low, the device is selected and the 12 address inputs are decoded to select one four-bit word out of 4K words. Read and Write operations on the memory cell are controlled by the /W input. With /E high, the device is deselected, the outputs are disabled and the power consumption is reduced to less than one-fourth of the active mode power with TTL levels and even lower with CMOS levels.

### READ CYCLE

A read cycle is defined as  $/W \geq V_{IH}$  min with  $/E \leq V_{IL}$  max. Read access time is measured from either /E going low or from valid address.

The READ CYCLE 1 waveform shows a read access that is initiated by a change in the address inputs while /E is low. The outputs remain active throughout READ CYCLE 1 and is valid at the specified address access time. The address inputs may change at access time and long as /E remains low, the cycle time is equal to the address access time.

The READ CYCLE 2 waveform shows a read access that is initiated by /E going low. As long as address is stable when /E goes low, valid data is at the outputs at the specified Chip Enable Access time. If address is not valid when /E goes low, the timing is as specified in READ CYCLE 1. Chip Enable access time is not affected by the duration of the deselect interval.

### WRITE CYCLE

The write cycle of the IMS1423M is initiated by the latter of /E or /W to transition from a high to a low. In the case of /W falling last, the output buffers will be turned on  $t_{ELOX}$  after the falling edge of /E (just as in a read cycle). The output buffers are then turned off within  $t_{WLOZ}$  of the falling edge of /W. During this interval, it is possible to have bus contention between devices with common I/O configurations. To avoid bus contention, input data should not be active until  $t_{WLOZ}$ .

WRITE CYCLE 1 waveform shows a write cycle terminated by /W going high. Data set-up and hold times are referenced to the rising edge of /W. When /W goes high at the end of the cycle with /E active, the outputs of the memory become active. The data from the memory will be the same as the input data unless the input data or address changes.

WRITE CYCLE 2 waveform shows a write cycle terminated by /E going high. Data set-up and hold times are referenced to the rising edge of /E. With /E high the outputs remain in the high impedance state.

## POWER DISTRIBUTION

The recommended power distribution scheme combines proper power trace layout and placement of decoupling capacitors to maintain the operating margins of the IMS1423M. The impedance in the decoupling path from the power pin through the decoupling capacitor to the ground pin should be kept to a minimum. The impedance of this path is determined by the series impedance of the power line inductance and the inductance and reactance of the decoupling capacitor.

Since the current transients associated with the operation of the high speed IMS1423M have very high frequency components, the line inductance is the dominating factor. To reduce the line inductance, the power trace and ground trace should be gridded or provided by separate power planes. The decoupling capacitor supplies energy for high frequency current transients and should be located as close to the devices with as short lead length as possible. The high frequency decoupling capacitor should have a value of 0.1 microfarad, and be placed between each row of devices in the array (see drawing). A larger tantalum capacitor, with a sufficient value to eliminate low frequency ripple, should be placed near the memory board edge connection where the power traces meet the backplane power distribution system. These larger capacitors provide bulk energy storage to prevent voltage drop due to the main supply being located off the memory board and at the end of a long inductive path.

The ground grid of the memory array should extend to the TTL periphery circuit. This will provide a solid ground reference for the TTL drivers and prevent loss of operating margin of the drivers due to differential ground noise.

## TERMINATION

Trace lines on a memory board in the array look to TTL driver signals like low impedance, unterminated transmission lines. In order to reduce or eliminate the reflections of the TTL signals propagating down the lines, especially low going TTL signals, line termination is recommended. The termination may be either series or parallel.

The recommended technique is to use series termination. The series termination technique has the advantage of drawing no DC current and using a minimum number of components. This is accomplished by placing a series resistor in the signal line at the output of the TTL driver to dampen the reflection on the line. The resistor should be placed as close to the driver package as is practical. The line should be kept short by placing the driver-termination combination close to the memory array.

Some experimentation will have to be done to find the proper value to use for the series termination to minimize reflections, but generally a series resistor in the 10 to 33 ohm range will be required. Because each design will result in a different signal impedance, a resistor of predetermined value may not properly match the signal path impedance. The proper value of resistance should therefore be selected empirically.

- Battery Backup Operation - 2V Data Retention (L version only)

## DESCRIPTION

The INMOS IMS1600M is a high performance 64Kx1 CMOS Static RAM processed in full compliance to MIL-STD-883C and guaranteed to operate over the full military temperature range. The IMS1600M provides maximum density and speed enhancements with the additional CMOS benefits of lower power and superior reliability.

The IMS1600M features fully static operation requiring no external clocks or timing strobes, and equal address access and cycle times. Additionally, the IMS1600M provides a Chip Enable ( $\bar{E}$ ) function that can be used to place the device into a low-power standby mode.

The IMS1601LM is a low power version offering battery backup data retention operating from a 2 volt supply.

WRITE CYCLE 2

# IMS1600M/IMS1601LM

## DEVICE OPERATION

The IMS1600M has two control inputs, a Chip Enable (/E) and Write Enable (/W), 16 address inputs (A0 -A15), a data in (D) and a data out (Q).

The /E input controls device selection as well as active and standby modes. With /E low, the device is selected and the 16 address inputs are decoded to select one memory cell out of 65,536. Read and Write operations on the memory cell are controlled by the /W input. With /E high, the device is deselected, the output is disabled and the power consumption is reduced to less than one-third of the active mode power with TTL levels and even lower with CMOS levels.

### READ CYCLE

A read cycle is defined as  $/W \geq V_{IH\ min}$  with  $/E \leq V_{L\ max}$ . Read access time is measured from either /E going low or from valid address.

The READ CYCLE 1 waveform shows a read access that is initiated by a change in the address inputs while /E is low. The output remains active throughout READ CYCLE 1 and is valid at the specified address access time. The address inputs may change at access time and long as /E remains low, the cycle time is equal to the address access time.

The READ CYCLE 2 waveform shows a read access that is initiated by /E going low. As long as address is stable when /E goes low, valid data is at the output at the specified Chip Enable Access time. If address is not valid when /E goes low, the timing is as specified in READ CYCLE 1. Chip Enable access time is not affected by the duration of the deselect interval.

### WRITE CYCLE

The write cycle of the IMS1600M is initiated by the latter of /E or /W to transition from a high to a low. In the case of /W falling last, the output buffer will be turned on  $t_{ELQ}$  after the falling edge of /E (just as in a read cycle). The output buffer is then turned off within  $t_{WLOZ}$  of the falling edge of /W. During this interval it is possible to have bus contention between devices with D and Q connected together in a common I/O configuration. To avoid bus contention input data should not be active until  $t_{WLOZ}$ .

WRITE CYCLE 1 waveform shows a write cycle terminated by /W going high. Data set-up and hold times are referenced to the rising edge of /W. When /W goes high at the end of the cycle with /E active, the output of the memory becomes active. The data from the memory will be the same as the input data unless the input data or address changes.

WRITE CYCLE 2 waveform shows a write cycle terminated by /E going high. Data set-up and hold times are referenced to the rising edge of /E. With /E high the output remains in the high impedance state.

### POWER DISTRIBUTION

The recommended power distribution scheme combines proper power trace layout and placement of decoupling capacitors to maintain the operating margins of the IMS1600M. The impedance in the decoupling path from the power pin through the decoupling capacitor to the ground pin should be kept to a minimum. The impedance of this path is determined by the series impedance of the power line inductance and the inductance and reactance of the decoupling capacitor.

Current transients associated with the operation of any high speed device have very high frequency components, so line inductance is the dominating factor. To reduce the line inductance, the power trace and ground trace should be gridded or provided by separate power planes. The decoupling capacitor supplies energy for high frequency current transients and should be located as close to the devices with as short lead length as possible. The high frequency decoupling capacitor should have a value of 0.1 microfarad and be placed between each row of devices in the array. A larger tantalum capacitor of a sufficient value to eliminate low frequency ripple, should be placed near the memory board edge connection where the power traces meet the backplane power distribution system. These larger capacitors provide bulk energy storage to prevent voltage drop due to the main supply being located off the memory board and at the end of a long inductive path. The ground grid of the memory array should extend to the TTL driver periphery circuit area. This will provide a solid ground reference for the TTL drivers and prevent loss of operating margin of the drivers due to differential ground noise.

**TERMINATION**

Trace lines on a memory board in the array look to TTL driver signals like low impedance, unterminated transmission lines. In order to reduce or eliminate the reflections of the TTL signals propagating down the lines, especially low going TTL signals, line termination is recommended. The termination may be either series or parallel.

The recommended technique is to use series termination. The series termination technique has the advantage of drawing no DC current and using a minimum number of components. This is accomplished by placing a series resistor in the signal line at the output of the TTL driver to

dampen the reflection on the line. The resistor should be placed as close to the driver package as is practical. The line should be kept short by placing the driver-termination combination close to the memory array.

Some experimentation will have to be done to find the proper value to use for the series termination to minimize reflections, but generally a series resistor in the 10 to 33 ohm range will be required. Because each design will result in a different signal impedance, a resistor of predetermined value may not properly match the signal path impedance. The proper value of resistance should therefore be selected empirically.

**DATA RETENTION** (L version only) ( $-55^{\circ}\text{C} \leq T_A \leq 125^{\circ}\text{C}$ )

# IMS1620M IMS1620LM CMOS High Performance 16K x 4 Static RAM MIL-STD-883C

## FEATURES

- INMOS' Very High Speed CMOS
- Advanced Process - 1.6 Micron Design Rules
- Full Military Temperature Operating Range (-55°C to + 125°C)
- MIL-STD-883C Processing
- 16K x 4 Bit Organization
- 45, 55 and 70 nsec Access Times
- Fully TTL Compatible
- Common Data Input & Output
- Three-state Output
- Power Down Function
- Single +5V  $\pm$  10% Operation
- 22-Pin, 300-mil DIP (JEDEC Std.)
- 22-Pin Ceramic LCC (JEDEC Std.)
- Battery Backup Operation - 2V Data Retention (L version only)

## DESCRIPTION

The INMOS IMS1620M is a high performance 16Kx4 CMOS Static RAM processed in full compliance to MIL-STD-883C and guaranteed to operate over the full military temperature range. The IMS1620M provides maximum density and speed enhancements with the additional CMOS benefits of lower power and superior reliability.

The IMS1620M features fully static operation requiring no external clocks or timing strobes, and equal address access and cycle times. Additionally, the IMS1620M provides a Chip Enable ( $\bar{E}$ ) function that can be used to place the device into a low-power standby mode.

The IMS1620LM is a low power version offering battery backup data retention operating from a 2 volt supply.

The IMS1624M is the functional equivalent of the IMS1620M with an added Output Enable function.

WRITE CYCLE 2

# IMS1620M/IMS1620LM

## DEVICE OPERATION

The IMS1620M has two control inputs, a Chip Enable (/E) and Write Enable (/W), 14 address inputs (A0 -A13), and four Data I/O pins.

The /E input controls device selection as well as active and standby modes. With /E low, the device is selected and the 14 address inputs are decoded to select one 4-bit word out of 16,384. Read and Write operations on the memory cells are controlled by the /W input. With /E high, the device is deselected, the outputs are disabled and the power consumption is reduced to less than one-third of the active mode power with TTL levels and even lower with CMOS levels.

### READ CYCLE

A read cycle is defined as  $/W \geq V_{IH\ min}$  with  $/E \leq V_{IL\ max}$ . Read access time is measured from either /E going low or from valid address.

The READ CYCLE 1 waveform shows a read access that is initiated by a change in the address inputs while /E is low. The outputs remain active throughout READ CYCLE 1 and is valid at the specified address access time. The address inputs may change at access time and long as /E remains low, the cycle time is equal to the address access time.

The READ CYCLE 2 waveform shows a read access that is initiated by /E going low. As long as address is stable when /E goes low, valid data is at the outputs at the specified Chip Enable Access time. If address is not valid when /E goes low, the timing is as specified in READ CYCLE 1. Chip Enable access time is not affected by the duration of the deselect interval.

### WRITE CYCLE

The write cycle of the IMS1620M is initiated by the latter of /E or /W to transition from a high to a low. In the case of /W falling last, the output buffers are turned on  $t_{ELQ}$  after the falling edge of /E (just as in a read cycle). The output buffers are then turned off within  $t_{WLQ}$  of the falling edge of /W. During this interval it is possible to have bus contention between devices with common I/O configurations. Therefore input data should not be active until  $t_{WLQ}$  to avoid bus contention.

WRITE CYCLE 1 waveform shows a write cycle terminated by /W going high. Data set-up and hold times are referenced to the rising edge of /W. When /W goes high at the end of the cycle with /E active, the output of the memory becomes active. The data from the memory will be the same as the input data unless the input data or address changes.

WRITE CYCLE 2 waveform shows a write cycle terminated by /E going high. Data set-up and hold times are referenced to the rising edge of /E. With /E high the outputs remain in the high impedance state.

## POWER DISTRIBUTION

The recommended power distribution scheme combines proper power trace layout and placement of decoupling capacitors to maintain the operating margins of the IMS1620M. The impedance in the decoupling path from the power pin through the decoupling capacitor to the ground pin should be kept to a minimum. The impedance of this path is determined by the series impedance of the power line inductance and the inductance and reactance of the decoupling capacitor.

Current transients associated with the operation of any high speed device have very high frequency components, so line inductance is the dominating factor. To reduce the line inductance, the power trace and ground trace should be gridded or provided by separate power planes. The decoupling capacitor supplies energy for high frequency current transients and should be located as close to the devices with as short lead length as possible. The high frequency decoupling capacitor should have a value of 0.1 microfarad and be placed between each row of devices in the array. A larger tantalum capacitor of a sufficient value to eliminate low frequency ripple, should be placed near the memory board edge connection where the power traces meet the backplane power distribution system. These larger capacitors provide bulk energy storage to prevent voltage drop due to the main supply being located off the memory board and at the end of a long inductive path. The ground grid of the memory array should extend to the TTL driver periphery circuit area. This will provide a solid ground reference for the TTL drivers and prevent loss of operating margin of the drivers due to differential ground noise.

**TERMINATION**

Trace lines on a memory board in the array look to TTL driver signals like low impedance, unterminated transmission lines. In order to reduce or eliminate the reflections of the TTL signals propagating down the lines, especially low going TTL signals, line termination is recommended. The termination may be either series or parallel.

The recommended technique is to use series termination. The series termination technique has the advantage of drawing no DC current and using a minimum number of components. This is accomplished by placing a series resistor in the signal line at the output of the TTL driver to

dampen the reflection on the line. The resistor should be placed as close to the driver package as is practical. The line should be kept short by placing the driver-termination combination close to the memory array.

Some experimentation will have to be done to find the proper value to use for the series termination to minimize reflections, but generally a series resistor in the 10 to 33 ohm range will be required. Because each design will result in a different signal impedance, a resistor of predetermined value may not properly match the signal path impedance. The proper value of resistance should therefore be selected empirically.

## DESCRIPTION

The INMOS IMS1624M is a high performance 16Kx4 CMOS Static RAM processed in full compliance to MIL-STD-883C and guaranteed to operate over the full military temperature range. The IMS1624M provides maximum density and speed enhancements with the additional CMOS benefits of lower power and superior reliability.

The IMS1624M features fully static operation requiring no external clocks or timing strobes, and equal address access and cycle times. The IMS1624M provides a Chip Enable (/E) function that can be used to place the device into a low-power standby mode. The IMS1624M also includes an Output Enable (/G) for fast access to data and enhanced bus contention control.

The IMS1624LM is a low power version offering battery backup data retention operating from a 2 volt supply.

**WRITE CYCLE 1**

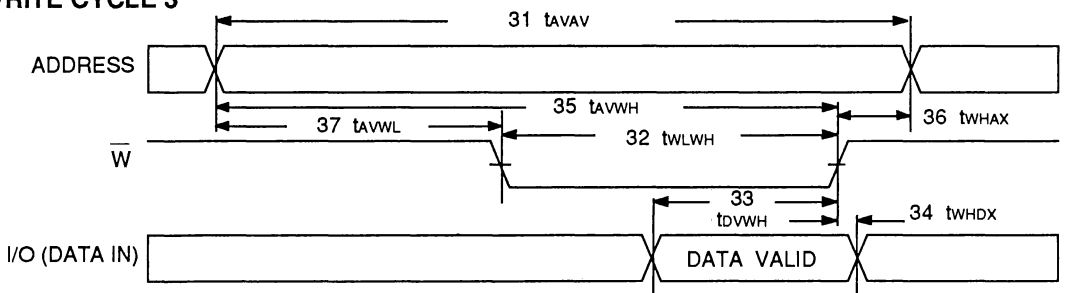

**IMS1624M/IMS1624M**

**WRITE CYCLE 2**

**WRITE CYCLE 3**

# IMS1624/IMS1624LM

## DEVICE OPERATION

The IMS1624M has three control inputs, Chip Enable (/E), Output Enable (/G) and Write Enable (/W), 14 address inputs (A0 -A13), and four Data I/O pins.

The /E input controls device selection as well as active and standby modes. With /E low, the device is selected and the 14 address inputs are decoded to select one 4-bit word out of 16,384. Read and Write operations on the memory cells are controlled by the /W and /G inputs. With /E high, the device is deselected, the outputs are disabled and the power consumption is reduced to less than one-fourth of the active mode power with TTL levels and even lower with CMOS levels.

### READ CYCLE

A read cycle is defined as  $/W \geq V_{IHmin}$  with /E and /G  $\leq V_{ILmax}$ . Read access time is measured from the latter of either /E or /G going low or from valid address.

The READ CYCLE 1 waveform shows a read access that is initiated by a change in the address inputs while /E and /G are low. The outputs remain active throughout READ CYCLE 1 and are valid at the specified address access time. The address inputs may change at access time and long as /E and /G remain low, the cycle time is equal to the address access time.

The READ CYCLE 2 waveform shows a read access that is initiated by the latter of /E or /G going low. As long as address is stable when /E goes low, valid data is at the outputs at the latter of specified Chip Enable Access or Output Enable Access times. If address is not valid when /E goes low, the timing is as specified in READ CYCLE 1. Chip Enable access time is not affected by the duration of the deselect interval.

### WRITE CYCLE

The write cycle of the IMS1624M is initiated by the latter of /E or /W to transition from a high to a low. In the case of /W falling last, the output buffers are turned on  $t_{ELOX}$  after the falling edge of /E if /G is already low (just as in a read cycle). The output buffers are then turned off within  $t_{WLOZ}$  of the falling edge of /W. During this interval it is possible to have bus contention between devices with common I/O configurations. Therefore input data should not be active until  $t_{WLOZ}$ . To avoid bus contention, the /G input can be held high throughout the write operation.

WRITE CYCLE 1 waveform shows a write cycle terminated by /W going high. Data set-up and hold times are referenced to the rising edge of /W. When /W goes high at the end of the cycle with /E active, the output of the memory becomes active (if /G is low). The data from the memory will be the same as the input data unless the input data or address changes.

WRITE CYCLE 2 waveform shows a write cycle terminated by /E going high. Data set-up and hold times are referenced to the rising edge of /E. With /E high the outputs remain in the high impedance state.

WRITE CYCLE 3 waveform shows a write cycle controlled by /W, with /G high and /E low throughout the cycle. As the outputs will not become active during this operation, maximum data bandwidth is provided by allowing very short write cycles and eliminating any bus contention considerations.

**POWER DISTRIBUTION**

The recommended power distribution scheme combines proper power trace layout and placement of decoupling capacitors to maintain the operating margins of the IMS1624M. The impedance in the decoupling path from the power pin through the decoupling capacitor to the ground pin should be kept to a minimum.

Current transients associated with the operation of any high speed device have very high frequency components, so line inductance is the dominating factor. To reduce the line inductance, the power trace and ground trace should be gridded or provided by separate power planes. The decoupling capacitor supplies energy for high frequency current transients and should be located as close to the devices with as short lead length as possible. The high frequency decoupling capacitor should have a value of 0.1 microfarad and be placed between each row of devices in the array. A larger capacitor to eliminate low frequency ripple should be placed near the edge connection where the power traces meet the backplane power. The larger capacitors provide bulk energy storage to prevent voltage drop due to the main supply being located off the memory board and at the end of a long inductive path. The ground grid of the memory array should extend to the TTL driver periphery circuit area to provide a solid ground reference for the TTL drivers and prevent loss of operating margin of the drivers due to differential ground noise.

**TERMINATION**

Trace lines on a memory board in the array look to TTL driver signals like low impedance, unterminated transmission lines. In order to reduce or eliminate the reflections of the TTL signals propagating down the lines, especially low going TTL signals, line termination is recommended. The termination may be either series or parallel.

The recommended technique is to use series termination. The series termination technique has the advantage of drawing no DC current and using a minimum number of components. This is accomplished by placing a series resistor in the signal line at the output of the TTL driver to dampen the reflection on the line. The resistor should be placed as close to the driver package as is practical. The line should be kept short by placing the driver-termination combination close to the memory array.

Some experimentation will have to be done to find the proper value to use for the series termination to minimize reflections, but generally a series resistor in the 10 to 33 ohm range will be required. Because each design will result in a different signal impedance, a resistor of predetermined value may not properly match the signal path impedance. The proper value of resistance should therefore be selected empirically.

Note f: Measured ±200mV from steady state output voltage. Output load capacitance is 5pF.

Note g:  $\bar{E}1$ ,  $\bar{E}2$ ,  $\bar{G}$  and  $\bar{W}$  must transition between V<sub>IH</sub> to V<sub>IL</sub> or V<sub>IL</sub> to V<sub>IH</sub> in a monotonic fashion.

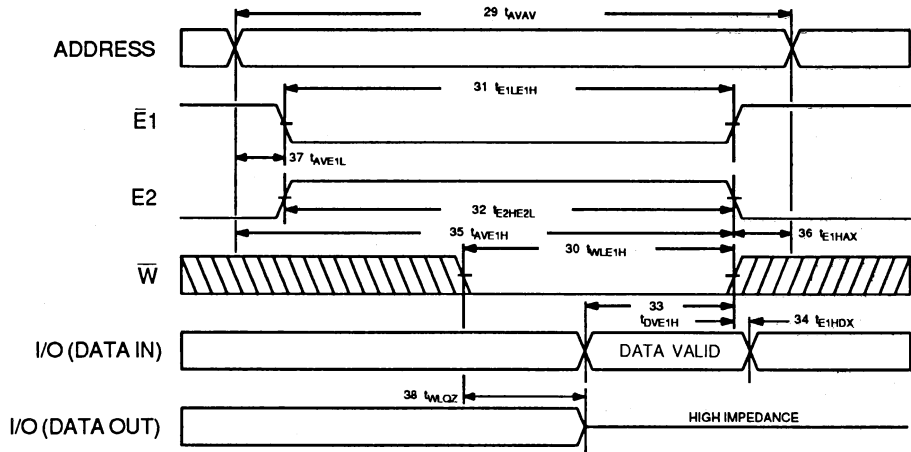

Note h:  $\bar{E}1$ ,  $\bar{E}2$  or  $\bar{W}$  must be ≥ V<sub>IH</sub> during address transitions.

Note i: If  $\bar{W}$  is low when the later of  $\bar{E}1$  goes low or  $\bar{E}2$  goes high, the outputs remain in high impedance state.

**WRITE CYCLE 1**

**WRITE CYCLE 2**

**WRITE CYCLE 3**

# IMS1630M/IMS1630LM

## DEVICE OPERATION

The IMS1630M has four control inputs: Chip Enable 1 (/E1), Chip Enable 2 (E2), Write Enable (/W), and Output Enable (/G). There are also thirteen address inputs (A0 - A12) and eight Data I/O lines (I/O 1 - I/O 8). The Enable inputs control device selection as well as active and standby modes. The /W input controls the mode of operation (Read or Write). The /G input controls only the state of the eight output drivers.

With both /E1 low and E2 high, the device is selected and the thirteen address inputs are decoded to select one 8-bit word out of 8k words. Read and Write operations on the memory cells are controlled by /W input. With either /E1 high or E2 low, the device is deselected, the output is disabled, and the power consumption is reduced to less than one-fourth of the active mode power. /G serves only to control the operation of the output drivers. When /G is high, the output drivers are in a high impedance state, independent of the /E1, E2 and /W inputs.

### READ CYCLE

A read cycle is defined as /W  $\geq$  V<sub>IH</sub> min. with /E1  $\leq$  V<sub>IL</sub> max. E2  $\geq$  V<sub>IH</sub> min. and /G  $\leq$  V<sub>IL</sub> max. Read access time is measured from the latter of either /E1 going low, E2 going high, valid address, or /G going low.

The READ CYCLE 1 waveform shows a read access that is initiated by a change in the address inputs while /E1 is low and E2 is high (with /G low). The output remains active throughout READ CYCLE 1 and is valid at the specified address access time. The address inputs may change at access time and the output remains valid for a minimum of t<sub>AXQX</sub>. As long as /E1 remains low and E2 is high, the cycle time is equal to the address access time.

The READ CYCLE 2 waveform shows a read access that is initiated by the latter of /E1 going low, E2 going high or /G going low. As long as address is stable when the latter of /E1 goes low or E2 goes high, valid data is at the output at the latter of t<sub>E1LQV</sub>, t<sub>E2HQV</sub> or t<sub>GLQV</sub>. If address is not valid when the latter of /E1 goes low or E2 goes high, the timing is as specified in READ CYCLE 1. Chip Enable access time is not affected by the duration of the deselect interval.

The /G signal controls the output buffer. /G is required to be low (along with /E1 low and E2 high) in order for I/O1 - I/O8 to be active.

### WRITE CYCLE

The write cycle of the IMS1630M is initiated by the latter of /E1 or /W to transition from a high to a low level or E2 transitioning from low to high. The /G control will eliminate bus contention if held high throughout the duration of the write cycle. If /G is low during a /W controlled write cycle (Write Cycle 1), the output buffer will be turned on by the latter of t<sub>E1LQX</sub> after the falling edge of /E1 or t<sub>E2HQX</sub> after the rising

edge of E2. The output buffer is then turned off within t<sub>WLOZ</sub> of the falling edge of /W. During this interval, it is possible to have bus contention between devices with common input/output connections. Therefore the recommended mode of operation is to keep /G high during the write cycle. During a write cycle, data on the inputs is written into the selected cells and the outputs are floating.

For any Write Cycle, t<sub>AVWL</sub>, t<sub>AVE1L</sub> or t<sub>AVE2H</sub> must be met, depending on whether /E1, E2 or /W is the last to transition. After either /W or /E1 goes high or E2 goes low to terminate the write cycle, addresses may change. If address set-up and hold times are not met, contents of other cells may be altered in unpredictable ways. The fidelity of the /W control signal is very important. Excessive ringing on high to low transitions may cause signals to rise above V<sub>IL</sub> max, violating the minimum /W pulse width specification - t<sub>WLWH</sub>.

WRITE CYCLE 1 waveform shows a write cycle terminated by /W going high. Data set-up and hold times are referenced to the rising edge of /W. When /W goes high while /E1 is low and E2 is high, the outputs remain in a high impedance (unless /G is low). If /G is low when /W goes high at the end of a write cycle the data read from the memory will be the same as the data just written into the memory. Thus, no data bus contention will occur.

WRITE CYCLE 2 waveform shows a write cycle terminated by the latter of /E1 going high or E2 going high. Data set-up and hold times are referenced to the latter of the rising edge of /E1 or the falling edge of E2. With either /E1 high or E2 low the outputs remain in the high impedance state.

WRITE CYCLE 3 waveform shows a write cycle controlled by /W, with /G high, /E1 low and E2 high throughout the cycle. This cycle will allow the maximum data bandwidth for the write operation while eliminating bus contention. This very short write pulse (t<sub>WLWH</sub>) allows high speed operation.

When using WRITE CYCLE 1, proper management of the /G control signal will avoid bus contention. If /G is low when /W goes high (with /E1 low and E2 high) the output buffers will be active t<sub>WQHGX</sub> after the rising edge of /W. Data out will be the same as the data just written, unless the address changes. If input data from the previous cycle is still valid after the address changes, contention may result. Contention may also result if the device is selected (/E1 low, E2 high, /G low) before /W goes low and input data is valid early in the cycle. The recommended mode of operation is to keep /G high except when reading data from the device, thus avoiding bus contention.

### TTL VS. CMOS INPUT LEVELS

The IMS1630M is fully compatible with TTL input levels. The input circuitry of the IMS1630M is designed for maximum speed and also for conversion of TTL level signals to the CMOS levels required for internal operation. The IMS1630M consumes less power when CMOS levels are used instead of TTL levels. The lower CMOS Icc specifications (Icc3 and Icc4) may be achieved by using CMOS levels. The power consumption will be lower at typical TTL levels than at the worst case levels.

**POWER DISTRIBUTION**

Recommended power distribution schemes combine proper power trace layout and placement of decoupling capacitors to maintain the wide operating margins of the IMS1630M. The impedance in the decoupling path from the Vcc power pin through the decoupling capacitor to the ground pin should be kept to a minimum. The impedance of this path is determined by the series impedance of the power line inductance and the inductance/reactance of the decoupling capacitor.

Current transients associated with the operation of high speed memories have very high frequency components, so line inductance is the dominating factor. To reduce the line inductance, the power trace and ground trace should be gridded or provided by separate power planes. The decoupling capacitor supplies energy for high frequency current transients and should be located as near the memory as possible, with the shortest lead lengths practical. The high frequency decoupling capacitor should have a minimum value of 0.1µF and be placed between the rows of memory devices in the array. A larger tantalum capacitor for low frequency current transients should be placed near the memory board edge connection where the power traces meet the backplane power distribution system. These larger capacitors provide bulk energy storage to prevent voltage drop due to the main supply being located off the memory board and at the end of a long inductive path. The ground grid of the memory array should extend to the TTL driver periphery circuit. This will provide a solid ground reference for the drivers and prevent loss of operating margin due to differential ground noise.

**TERMINATION**

Trace lines on a memory board in the array look to TTL driver signals like low impedance, unterminated transmission lines. In order to reduce or eliminate the reflections of the TTL signals propagating down the lines, especially low going TTL signals, line termination is recommended. The termination may be either series or parallel.

The recommended series termination technique uses no DC current and a minimum number of components. This is accomplished by placing a series resistor in the signal line at the output of the TTL driver to dampen the reflection on the line. The termination resistor should be placed as close to the driver package as possible. The line should be kept short by placing the driver-termination combination close to the memory array.

Some experimentation will have to be done to find the proper value to use for the series termination to minimize reflections, but generally a series resistor in the 10 to 33ohm range will be required. Because the characteristic impedance of each layout will be different, it is necessary to select the proper value of this resistor by trial and error. A resistor of predetermined value may not properly terminate the transmission line.

Proper power distribution techniques, including adequate use of decoupling capacitors, and proper termination of TTL drive outputs are some of the most important yet basic guidelines that need to be followed when designing and building a memory board. The guidelines are intended to maintain the operating margins of all devices on the memory board by providing a quiet environment free of noise spikes, undershoot, and excessive ringing. It is wise to verify signal fidelity by observation utilizing a wideband oscilloscope and probe.

## High Performance 64Kx1 Dynamic RAM MIL-STD-883C

### FEATURES

- Full Military DRAM Temperature Operating Range (-55°C to +110°C)
- MIL-STD-883C Processing
- 100, 120 and 150nsec RAS Access Times
- Cycle Times of 160, 190 and 230ns
- Low Power:
  - 28mW Standby
  - 358mW Active (350ns Cycle Time)
  - 468mW Active (160ns Cycle Time)
- On-Chip Refresh using CAS-before-RAS
- 4ms / 256 Cycle Refresh, Pin 1 left as N/C for 256K expansion
- RAS-Only Refresh Capability
- D<sub>OUT</sub> Hold under CAS control
- JEDEC Standard 16-pin Configuration
- Read, Write Read-Modify-Write Capability both on Single Bit and in Nibble Mode Operation

### DESCRIPTION

The INMOS IMS2600M 64Kx1 Dynamic RAM is processed in full compliance to MIL-STD-883C. This RAM is fabricated with INMOS' proprietary NMOS technology and utilizes innovative circuit techniques to achieve high performance, low power and wide operating margins.

Multiplexed addresses allows the IMS2600M to be packaged in the conventional 16 pin DIP. Additionally, the IMS2600M features new functional enhancements that make it more versatile than previous dynamic RAMs. CAS-before-RAS Refresh is an "on-chip" refresh mechanism that is upward compatible to 256K generations because pin 1 is left as a no connect. "Nibble Mode" also provides high speed serial access of 4 bits of data, thus providing the system equivalent of 4-way interleaving on chip.

The IMS2600M is fully TTL compatible on all inputs and the output, and operates from a single +5V ±10% power supply.

The IMS2600M is a high speed VLSI RAM intended for military applications which demand high density as well as superior performance and reliability.

## DEVICE OPERATION

The IMS2600M contains 65536 ( $2^{16}$ ) bits of information as 256 ( $2^8$ ) rows by 256 ( $2^8$ ) columns. The sixteen addresses for unique bit selection are time-division multiplexed over eight address lines under control of the Row Address Strobe ( $\overline{RAS}$ ) and Column Address Strobe ( $\overline{CAS}$ ) clocks. The normal sequence of  $\overline{RAS}$  and  $\overline{CAS}$  requires that  $\overline{CAS}$  is high as  $\overline{RAS}$  goes low. This causes the eight address inputs to be latched and decoded for selection of one of the 256 rows. The row addresses must be held for the specified period [ $t_{RAH}$  (min)] and then they may be switched to the appropriate column address. After the column addresses are stable for the specified column address setup time,  $\overline{CAS}$  may be brought low. This causes the eight address inputs to be latched and used to select a single column in the specified row. The cycle is terminated by bringing  $\overline{RAS}$  high. A new cycle may be initiated after  $\overline{RAS}$  has been high for the specified precharge interval [ $t_{RP}$  (min)].  $\overline{RAS}$  and  $\overline{CAS}$  must be properly overlapped and once brought low they must remain low for their specified pulse widths.

## READ CYCLE

A read cycle is performed by sequencing  $\overline{RAS}$  and  $\overline{CAS}$  as described above while holding the  $\overline{WE}$  input high during the period when  $\overline{RAS}$  and  $\overline{CAS}$  are both low. The read access time will be determined by the actual timing relationship between  $\overline{RAS}$  and  $\overline{CAS}$ . If  $\overline{CAS}$  goes low within the specified  $\overline{RAS}$ -to- $\overline{CAS}$  delay [ $t_{ACD}$  (max)], then the access time will be determined by  $\overline{RAS}$  and be equal to  $t_{RAC}$  (max). If  $\overline{CAS}$  occurs later than  $t_{ACD}$  (max) then the access time is measured from  $\overline{CAS}$  and will be equal to  $t_{CAC}$  (max).

## WRITE CYCLE

The IMS2600M will perform three types of write cycles: Early-Write, Late-Write or Read-Modify-Write. The difference between these cycles is that on an Early-Write  $D_{OUT}$  will remain open and on a Late-Write or Read-Modify-Write  $D_{OUT}$  will reflect the contents of the addressed cell before it was written.

The type of write cycle that is performed is determined by the relationship between  $\overline{CAS}$  and  $\overline{WE}$ . For Early-Write cycles  $\overline{WE}$  occurs before  $\overline{CAS}$  goes low, and  $D_{IN}$  setup is referenced to the falling edge of  $\overline{CAS}$ . For Late-Write or Read-Modify-Write cycles  $\overline{WE}$  occurs after  $\overline{CAS}$ , and  $D_{IN}$  setup is referenced to the falling edge of  $\overline{WE}$ .

The choice of write cycle timing is usually very system dependent and the different modes are made available to accommodate these differences. In general, the Early-Write timing is most appropriate for systems that have a bidirectional data bus. Because  $D_{OUT}$  remains inactive during Early-Write cycles, the  $D_{IN}$  and  $D_{OUT}$  pins may be tied together without bus contention.

## DEVICE SELECTION AND OUTPUT CONTROL

Selection of a memory device for a read or write operation requires that both  $\overline{RAS}$  and  $\overline{CAS}$  be sequenced. A device is not selected if  $\overline{RAS}$  is sequenced while  $\overline{CAS}$  remains high or if  $\overline{CAS}$  is sequenced while  $\overline{RAS}$  remains high. The device must receive a properly overlapped  $\overline{RAS}/\overline{CAS}$  sequence to be selected.

Once a device is selected the state of  $D_{OUT}$  becomes

entirely controlled by  $\overline{CAS}$ . If  $\overline{CAS}$  remains low when  $\overline{RAS}$  goes high,  $D_{OUT}$  will remain in the state it was in when  $\overline{RAS}$  went high. The output will remain unchanged even if a  $\overline{RAS}$  sequence occurs while  $\overline{CAS}$  is held low.

## REFRESH

The IMS2600M remembers data by storing charge on a capacitor. Because the charge will leak away over a period of time it is necessary to access the data in the cell (capacitor) periodically in order to fully restore the stored charge while it is still at a sufficiently high level to be properly detected. For the IMS2600M any  $\overline{RAS}$  sequence will fully refresh an entire row of 256 bits. To ensure that all cells remain sufficiently refreshed, all 256 rows must be refreshed every 4 ms.

The addressing of the rows for refresh may be sourced either externally or internally. If the row refresh addresses are to be provided from an external source,  $\overline{CAS}$  must be high when  $\overline{RAS}$  goes low. If  $\overline{CAS}$  is high when  $\overline{RAS}$  goes low, any type of cycle (Read, Write, Read-Modify-Write or  $\overline{RAS}$  only) will cause the addressed row to be refreshed.

If  $\overline{CAS}$  is low when  $\overline{RAS}$  falls, the IMS2600M will use an internal 8-bit counter as the source of the row addresses and will ignore the address inputs. This  $\overline{CAS}$ -before- $\overline{RAS}$  refresh mode is a refresh-only mode and no data access is allowed. Also,  $\overline{CAS}$ -before- $\overline{RAS}$  refresh does not cause device selection and the state of  $D_{OUT}$  will remain unchanged.

## NIBBLE MODE

The IMS2600M is designed to allow high-speed serial read, write or read-modify-write access of 2, 3 or 4 bits of data. The bits of data that may be accessed during Nibble Mode are determined by the eight row addresses and the most significant 6 bits of the column address. The low-order 2 bits of the column address ( $A_3, A_6$ ) are used to select one of the 4 nibble bits for initial access. After the first bit is accessed the remaining nibble bits may be accessed by bringing  $\overline{CAS}$  high then low (toggle) while  $\overline{RAS}$  remains low. Toggling  $\overline{CAS}$  causes  $A_3$  and  $A_6$  to be incremented internally while all other address bits are held constant and makes the next nibble bit available for read, write and/or read-modify-write access (See Table 1 for example). If more than 4 bits are accessed during Nibble Mode, the address sequence will begin to repeat. If any bit is written during an access, the new value will be read on any subsequent accesses.

In Nibble Mode, read, write and read-modify-write operations may be performed in any desired combination: (e.g., first bit read, second bit write, third bit read-modify-write, etc.)

**Table 1**  
**NIBBLE MODE ADDRESSING SEQUENCE EXAMPLE**

SEQUENCE	NIBBLE BIT	ROW ADDRESSES	COLUMN ADDRESSES	EXAMPLE
			$A_3, A_6$	
$\overline{RAS}/\overline{CAS}$	1	10101010	10101010	generated externally
toggle $\overline{CAS}$	2	10101010	10101011	
toggle $\overline{CAS}$	3	10101010	10101000	generated internally
toggle $\overline{CAS}$	4	10101010	10101001	
toggle $\overline{CAS}$	1	10101010	10101010	sequence repeats

**ABSOLUTE MAXIMUM RATINGS\***

Voltage on VCC relative to VSS.....-1.0 to +7.0V  
 Storage Temperature (Ceramic)....-65° C to +150°C  
 Power Dissipation.....1W  
 Short Circuit Output Current.....50mA  
 (One Second Duration)

\*Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

**NOTES:**

- e: t<sub>RCD</sub> (max) is a derived parameter; t<sub>RCD</sub> (max) = t<sub>RAC</sub> (max) - t<sub>CAC</sub> (max); t<sub>RCD</sub> (min) is a restrictive parameter due to CAS-before-RAS refresh.
- f: t<sub>OFF</sub> (max) is defined as the time at which the output achieves the open circuit condition.
- h: Assumes that t<sub>RCD</sub> ≤ t<sub>RCD</sub> (max). If t<sub>RCD</sub> is greater than the maximum recommended value shown in this table, t<sub>RAC</sub> will increase by the amount that t<sub>RCD</sub> exceeds t<sub>RCD</sub> (max).
- i: Assumes that t<sub>RCD</sub> ≥ t<sub>RCD</sub> (max).
- j: Operation within the t<sub>RCD</sub> (max) limit ensures that t<sub>RAC</sub> (max) can be met. t<sub>RCD</sub> (max) is specified as a reference point only; if t<sub>RCD</sub> is greater than the specified t<sub>RCD</sub> (max) limit, then access time is determined exclusively by t<sub>CAC</sub>.
- k: Either t<sub>RRH</sub> or t<sub>RCH</sub> must be satisfied for a Read cycle.
- l: These parameters are referenced to CAS leading edge in Early-Write cycles, and to WE leading edge in Read-Write or Read-Modify-Write cycles.

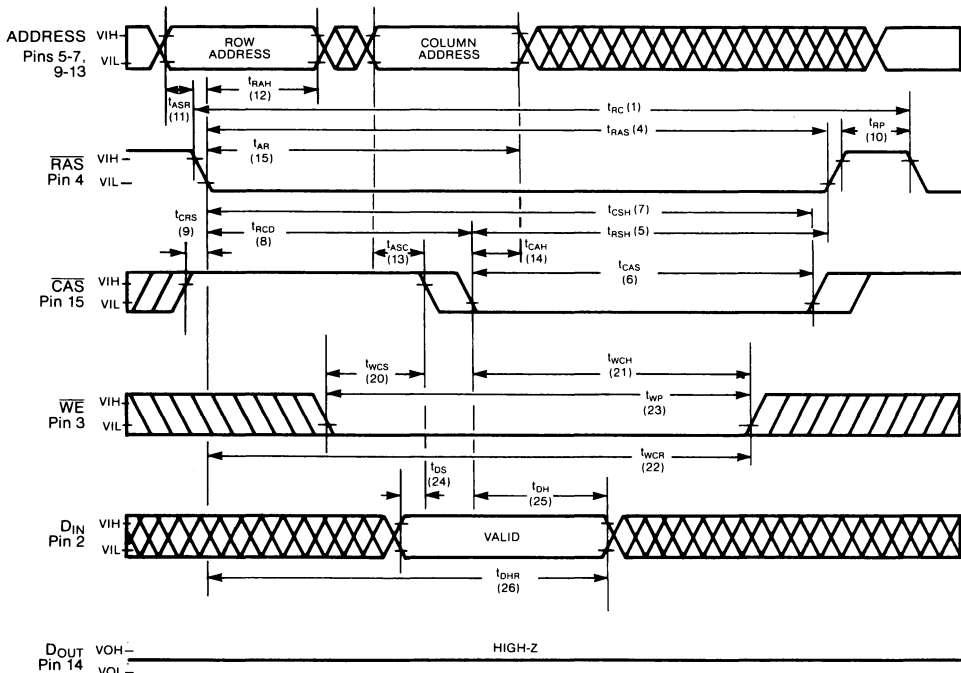

- m: t<sub>WCS</sub>, t<sub>CWD</sub>, and t<sub>RWD</sub> are restrictive operating parameters in Read-Write and Read-Modify-Write cycles only. If t<sub>WCS</sub> ≥ t<sub>WCS</sub> (min) the cycle is an Early-Write cycle and the data output will remain open circuit throughout the entire cycle. If t<sub>CWD</sub> ≥ t<sub>CWD</sub> (min) and t<sub>RWD</sub> ≥ t<sub>RWD</sub> (min) the cycle is a Read-Write and the data output will contain data read from the selected cell. If neither of the above conditions is met the condition of the data\_out is indeterminate at access time and remains so until CAS returns to V<sub>IH</sub>.
- n: The transition time specification applies for all input signals. In addition to meeting the transition rate specification, all input signals must transit between V<sub>IH</sub> and V<sub>IL</sub> (or between V<sub>IL</sub> and V<sub>IH</sub>) in a monotonic manner. Transition time measured between V<sub>IL</sub> (max) and V<sub>IH</sub> (min).

### APPLICATION

To ensure proper operation of the IMS2600M in a system environment it is recommended that the following guidelines on board layout and power distribution be followed.

### POWER DISTRIBUTION

The recommended power distribution scheme combines proper trace layout and placement of decoupling capacitors. The impedance in the decoupling path from the power pin (8) through the decoupling capacitor, to the ground pin (16) should be kept to a minimum. The impedance of this path is determined by the series impedance of the power line and the decoupling capacitor.

To reduce the power line impedance, it is recommended that the power trace and ground trace be gridded or provided by separate power planes. To prevent loss of signal margins due to differential ground noise, the ground grid of the memory array should be extended to the TTL drivers in the peripheral circuitry. A high-frequency decoupling capacitor with a value of  $0.1\mu\text{F}$  should be placed between the rows of memory devices in the array. A larger tantalum capacitor with a value between  $22\mu\text{F}$  and  $47\mu\text{F}$  should be placed near the memory board edge connection where the power traces meet the backplane power distribution system. These large capacitors provide bulk energy storage to prevent voltage drop due to the main supply being located off the memory board and at the end of a long inductive path.

### TERMINATION

Trace lines on a memory board in the array look to TTL driver signals like low impedance, unterminated transmission lines. In order to reduce or eliminate the reflections of the TTL signals propagating down the lines, especially low-going TTL signals, line termination is recommended. The termination may be either parallel or series but the series termination technique has the advantages of drawing no DC current and using a minimum of components. The recommended technique is to use series termination.

A series resistor in the signal line at the output of the TTL driver to match the source impedance of the TTL driver to the signal line will dampen the reflections on the line. The line should be kept short with the driver/termination combination close to the memory array. Some experimentation will have to be done to find the proper value to use for the series termination to minimize reflections, but generally a series resistor in the  $10\Omega$  to  $30\Omega$  range will be required.

Proper power distribution techniques, including adequate use of decoupling capacitors, along with proper termination of TTL driver outputs, are among the most important, yet basic guidelines to be followed. These guidelines are intended to maintain the operating margins of all devices on the memory board by providing a quiet environment relatively free of noise spikes and signal reflections.

# **military qualification**

## **A Military Qualification**

### **A.1 Military qualification**

#### **A.1.1 Military product program**

The INMOS Military Product Program has been developed to meet the increasingly demanding requirements for Class B memory product in accordance with paragraph 1.2.1 of MIL-STD-883 'Provisions for the use of MIL-STD-883 in conjunction with compliant non-JAN devices'.

All INMOS MIL-STD-883 Class B product is screened to the specifications of Method 5004 with electrical testing executed over the military temperature range -55°C to +125°C.

Each inspection lot is subjected to the requirements of method 5004 Group A Electrical sampling and Group B Mechanical and Environmental sample testing. Additionally, all new product and changes to product as defined in MIL-M-38510 paragraph 3.4.2 [major changes] is qualified per method 5005 Group C [Die related] and Group D [Package related tests]. Periodic Conformance Testing is carried out per the requirements of MIL-STD-883 paragraph 1.2.1 for all relevant die families and package types.

INMOS MIL-STD-883 product in hermetically sealed packages includes an organic die overcoat [RTV] for enhanced alpha-particle protection. INMOS uses the Alternate Die Inspection procedure in Method 5004 paragraph 3.3.1 which allows for a low magnification visual inspection but requires an additional Temperature Cycle screen in assembly, followed by a voltage stress and low level leakage electrical screen in final test.

Full details of INMOS' military processing are included in INMOS Specification 49-9047, 'General Military Processing Specification', which may be obtained upon request from INMOS.

Suitability for use in specific applications should be determined by using the guidelines of MIL-STD-454.

By specifying an INMOS military product, the user is assured of a product which has been subjected to the full Screening and Quality Conformance requirements of paragraph 1.2.1 of MIL-STD-883 in addition to the full range of in-house process, test and quality control functions designed to enhance the quality and reliability of all INMOS products.

#### **A.1.2 Standard military drawing program**

The INMOS Standard Military Drawing (SMD) program was introduced in 1986 to supply military and governmental products. The SMD Program was implemented by the US Government and its associated subcontractors to provide the industry with a single SMD for each military IC requirement. These SMDs are intended to replace the multiplicity of Source Control Drawings (SCDs) generated by each contractor. Components specified according to the SMD Program are standard military MIL-STD-883 compliant devices.

INMOS, and other IC manufacturers, initiate the development of SMDs in conjunction with military contractors who have significant demand for the particular device. Together they initiate an SMD proposal which the Defense Electronics Supply Center (DESC) screens and approves. Accepted SMDs are then circulated by DESC to industry vendors and consumers to obtain multiple sources and registered users.

INMOS fully supports the Standard Military Drawing Program and the DESC efforts to expand its usage.

Appendix B, which details cross reference information, lists each approved INMOS product by its SMD number and the corresponding INMOS part number.

# quality and reliability

## **C Quality and Reliability**

The INMOS quality programme is set up to be attentive to every phase of the semiconductor product life cycle. This includes specific programmes in each of the following areas:

- Total Quality Control (TQC)
- Quality and Reliability in Design
- Document Control
- New Product Qualification
- Product Monitoring Programme
- Production Testing and Quality Monitoring Procedure

### **C.1 Total quality control (TQC) and reliability programme**

Our objective to continuously build improved quality and reliability into every INMOS part has resulted in a comprehensive Quality/Reliability Programme of which we are proud. This programme demonstrates INMOS' serious commitment to supporting the quality and reliability needs of the electronics marketplace.

INMOS is systematically shifting away from a traditional screening approach to quality control and towards one of building in Experimental Design quality through Statistical Process Control (SPC). This new direction was initiated with a vigorous programme of education and scientific method training.

In the first year of the programme approximately 80 INMOS employees worldwide received thorough SPC training. This training has been extended to cover advanced SPC and experimental design. Some of the courses taught are listed below:

- Experimental Design Techniques
- Statistical Process Control Methods
- Quality Concepts
- Problem Solving Techniques
- Statistical Software Analysis Techniques

Today INMOS utilizes experimental design techniques and process control/monitoring throughout its development and manufacturing cycles. The following TQC tools are currently supported by extensive databases and analysis software.

1. Pareto charts
2. Cause/Effect Diagrams
3. Process Flow Charts
4. Run Charts
5. Histograms
6. Correlation Plots
7. Control Charts
8. Experimental Design
9. Process Capability Studies

### **C.2 Quality and reliability in design**

The INMOS quality programme begins with the design of new INMOS products. The following procedures are examples from the INMOS programme to design quality and reliability into every product.

Innovative design techniques are employed to achieve product performance using, whenever possible, state of the art techniques. For example, INMOS uses 300 nm gate oxides on its high performance graphics, SRAM and MICRO products to obtain the reliability inherent in the thicker gate oxide. In addition, circuit design engineers work hand in hand with process engineers to optimise the design for the process and the process for the product family. The result is a highly reliable design implemented in a process technology

achievable within manufacturing.

INMOS products are designed to have parametric margins beyond the product target specifications. The design performance is verified using simulations of circuit performance over voltage and temperature values beyond those of specified product operation, including verification beyond the military performance range. In addition, the device models are chosen to ensure tolerance to wide variations in process parameters beyond those expected in manufacture.

The design process includes consideration of quality issues such as signal levels available for sensing, reduction of internal noise levels, stored data integrity and testability of all device functions. Electro-static damage protection techniques are included in the design with input protection goals of 2K volts for MIL-STD-883 testing methods. Specific customer requirements can be met by matching their detailed specifications against INMOS designed in margins.

The completion of the design includes the use of INMOS computer aided design software to fully check and verify the design and layout. This improves quality as well as ensuring the timely introduction of new products.

### **C.3 Document control**

The Document Control Department maintains control over all manufacturing specifications, lot travellers, procurement specifications and drawings, reticle tapes and test programmes. New specifications and changes are subject to approval by the Engineering and Manufacturing managers or their delegates. Change is rigorously controlled through an Engineering Change Notice procedure, and QA department managers screen and approve all such changes.

An extensive archiving system ensures that the history of any Change Notice is readily available.

Document Control also has responsibility for controlling in-line documentation in all manufacturing areas which includes distribution of specifications, control of changes and liaison with production control and manufacturing in introducing changed procedures into the line.

Extensive use is made of computer systems to control documentation on an international basis.

### **C.4 New product qualification**

INMOS performs a thorough internal product qualification prior to the delivery of any new product, other than engineering samples of prototypes to customers.

Care is taken to select a representative sample from the final prototype material. This typically consists of three different production lots. Testing is then done to assure the initial product reliability levels are achieved. Product qualifications are done in accordance with MIL-STD-883, methods 5004 and 5005, or CECC/BS9000.

The initial INMOS qualification data, and the ongoing monitor data can be very useful in the user qualification decision process. INMOS also has a very successful history of performing customer qualification testing in-house and performing joint qualification programmes with customers. INMOS remains committed to joint customer/vendor programmes.

### **C.5 Product monitoring programme**

At the levels of quality and reliability performance required today (low PPM and FIT levels), it is essential that a large statistically significant, current product database be maintained. One of the programmes that INMOS uses to accomplish this is the Product Monitoring Programme (PMP).

The PMP is a comprehensive ongoing programme of reliability testing. A small sample is pulled from production lots of a particular part type. This population is then used to create the specific samples to put on the various operating and environmental tests. Tests run in this programme include extended temperature operating life, THB and temperature cycle. Efforts are continuing to identify and correlate more accelerated

## **C Quality and Reliability**

tests to be used in the PMP.

### **C.6 Production testing and quality monitoring procedure**

#### **C.6.1 Reliability testing**

INMOS' primary reliability test method is to bias devices at their maximum rated operating power supply level in a 140° C ambient temperature. A scheme of time varying input signals is used to simulate the complete functional operation of the device. The failure rate is then computed from the results of the operating life test using Arrhenius modelling for each specific failure mechanism known. The failure rate is reported at a temperature that is a typical worst case application environment and is expressed in units of FITs where 1 FIT = 1 Fail in 10E9 device hours, (100 FIT = 0.01%/1000 Hrs). The current database enables the failure rate to be valid over various environmental conditions.

The failure rate goal for INMOS products is 100 FITs or less at product introduction with a 50 FIT level to be attained within one year.

For plastic packaged product, additional testing methods and reliability indices become important. Humidity testing is used to evaluate the relative hermeticity of the package, and thermal cycling tests are used principally to evaluate the durability of the assembly (e.g. die/bond attach).

The Humidity Test comprises of temperature, humidity, bias (THB) at 85°C, 85% Relative Humidity, and a 5V static bias configuration selected to maintain the component in a state of minimum power dissipation and enhance the formation of galvanic corrosion. INMOS reliability goals have always been to meet or better the current 'industry standards' and a target of less than 1% failures through 1000 hours of THB at 90% confidence has been set.

The Thermal Cycling tests are performed from -65°C to + 150 °C for 500-1000 cycles, with no bias applied. Thermal Shock tests using a liquid to liquid (Freon) method are cycled between -55°C and + 125 °C. The INMOS Reliability qualification and monitoring goal for the above tests is less than 1% failures at 90% confidence.

#### **C.6.2 Production testing**

Electrical testing at INMOS begins while the devices are still in wafer form before being divided into individual die. While in this form, two different types of electrical test are performed.

The Parametric Probe test is to verify that the individual component parameters are within their design limits. This is accomplished by testing special components on the wafer. The results of these tests provide feedback to our wafer fab manufacturing facilities which allows them to ensure that the components used in the actual devices perform within their design limits. This testing is performed on all lots which are processed, and any substandard wafers discarded. These components are placed in the scribe streets of the wafer so they are destroyed in the dicing operation when they are not of any further use. By placing them there, valuable chip real estate is saved, thereby holding down cost while still providing the necessary data.

The Electrical Probe test performed on all wafers is the test of each individual circuit or chip on every wafer. The defective dice are identified so they may be later discarded after the wafer has been separated into individual die. This test fully exercises the circuits for all AC and DC datasheet parameters in addition to verifying functionality.

After the dice have been assembled into packages they are again tested in our Final Test operation. In a mature product the typical flow is:

- Preburn-in test
- Burn-in at 140°C
- Final test

- PDA (Percent Defect Allowed)
- Device Symbolisation
- QA Final Acceptance

The temperature setting used for hot testing is selected so that the junction temperature is the same as it would be after thermal stabilisation occurred in the specified environment. This is calculated using the hot temperature power dissipation along with the thermal resistance of the package used. All INMOS product is electrically tested and burned-in prior to shipment. Historically, the industry has selected burn-in times using the MIL Standards as a guide (when the market would support the cost) or on a 'best guess' basis dominated by cost considerations. Whereas INMOS invoke a burn-in reduction exercise to ensure the reduced time has no reliability impact.

### C.6.3 Quality monitoring procedure

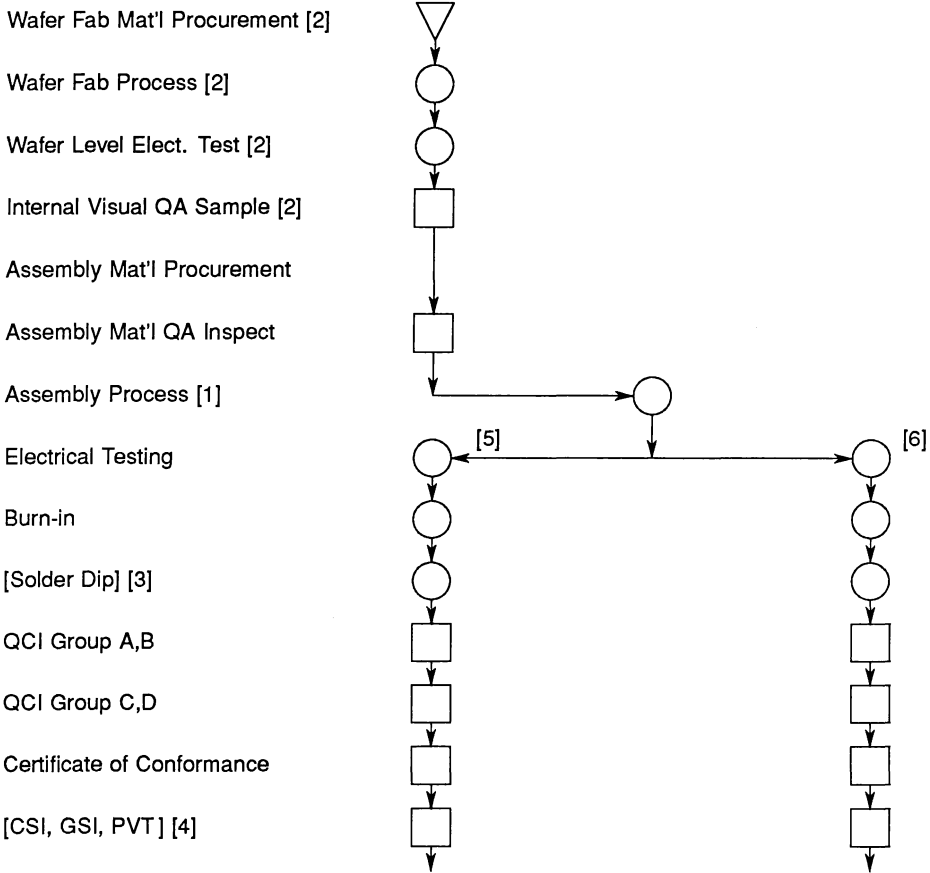

In the Outgoing Quality Monitoring programme, random samples are pulled from lots, that have been successfully tested to data sheet criteria. Rejected lots are 100% retested and more importantly, failures are analysed and corrective actions identified to prevent the recurrence of specific problems.

The extensive series of electrical tests with the associated Burn-in PDA limits and Quality Assurance tests ensure we will be able to continue to improve our high quality and reliability standards.

SRAM Parts

# general information

## D General Information

### D.1 Thermal considerations

#### D.1.1 Thermal resistance

An electronic circuit can be characterised by its resistance (impedance), potential differences, current sources, capacitance and time constants. A thermal circuit can be expressed in terms of thermic resistance, thermic differences, heat sources, thermic capacitances and thermic time constants.

The ability of the device package to conduct heat from the chip to the environment is expressed in terms of thermal resistance. The term normally used is  $\theta_{ja}$ , written  $\theta_{ja}$ . It is often separated into two components:

The thermal resistance from the Junction to Case  $\theta_{jc}$ ,  
and

The thermal resistance from Case to Ambient  $\theta_{ca}$ .

$\theta_{ja}$  represents the total resistance to heat flow from the Chip to Ambient. It is expressed as follows:

$$\theta_{jc} + \theta_{ca} = \theta_{ja}$$

#### D.1.2 Junction temperature

Junction Temperature ( $T_j$ ) of a powered integrated circuit is the temperature measured at the substrate diode. When the chip is powered, the heat generated causes the  $T_j$  to rise above the ambient temperature ( $T_a$ ).  $T_j$  is calculated by multiplying the power dissipation of the device by the thermal resistance of the package and adding the ambient temperature to the result.

$$T_j = (Pd.\theta_{ja}) + T_a$$

#### D.1.3 K-Factor and $\theta_{ja}$ Measurement

There is a simple way of measuring the thermal resistance of  $\theta_{ja}$  of any package. The basic idea is to use the forward voltage drop of a calibrated diode to measure the change in junction temperature due to a known power dissipation. The thermal resistance can be calculated using the following equation:

$$\theta_{ja} = \frac{\Delta T_j}{Pd} = \frac{T_j - T_a}{Pd}$$

Now, If the current through the diode is constant and the temperature changes, we can calculate the temperature coefficient (also called the K-Factor) using the following equation:

$$K = \frac{T_2 - T_1}{V_{F2} - V_{F1}}$$

K = temperature coefficient ( $^{\circ}/mV$ )

$T_2$  = higher temperature test ( $^{\circ}C$ )

$T_1$  = lower temperature test ( $^{\circ}C$ )

$V_{F2}$  = forward voltage at  $T_2$

$V_{F1}$  = forward voltage at  $T_1$

#### D.1.4 Factors affecting $\theta_{ja}$

There are several factors which affect the thermal resistance of any IC package. Effective thermal management requires a sound understanding of all these variables. Package variables include the leadframe design and materials, the plastic or the ceramic used to encapsulate the device and to a lesser extent other variables such as the die and die attach methods. Other factors that have a significant impact on  $\theta_{ja}$  include

## D General Information

the substrate upon which the IC is mounted, the density of the layout, the air gap between the package and the substrate, the number and length of traces on the board, the use of thermally conducting epoxies and external cooling methods.

The following list is a summary of  $\theta_{ja}$ ,  $\theta_{jc}$ , and  $\theta_{jx}$  for the current range of device types and corresponding package styles where data exists. Thermal resistance is expressed in degC/  $W_{att}$ .

Note:  $\theta_{jx}$  takes into account the 400 linear ft/min moving air measurement condition often specified/required by customers. It is obtained by multiplying  $\theta_{ja}$  by 0.6.  $\theta_{jc}$  is measured from the hottest part of the case.
